Symplectic geometry of quantum noise

Leonid Polterovich

March 8, 2013

Abstract

We discuss a quantum counterpart, in the sense of the Berezin-Toeplitz quantization, of certain constraints on Poisson brackets coming from "hard" symplectic geometry. It turns out that they can be interpreted in terms of the quantum noise of observables and their joint measurements in operational quantum mechanics. Our findings include various geometric mechanisms of quantum noise production and a noise-localization uncertainty relation. The methods involve Floer theory and Poisson bracket invariants originated in function theory on symplectic manifolds.

1 Introduction

The main theme of the present paper is an interaction between "hard" symplectic geometry and operational quantum mechanics, where the role of observables is played by positive operator valued measures (POVMs) [8]. We focus on POVMs coming from partitions of unity of a classical phase space, that is a closed symplectic manifold, under the Berezin-Toeplitz quantization. Such POVMs, considered earlier in [32], model a *registration procedure*, a statistical procedure which can be considered as an attempt to localize the system in the phase space and which is closely related to approximate quantum measurements. Certain constraints on Poisson brackets coming from symplectic geometry can be interpreted in terms of the quantum noise of these observables and their joint measurements. Our findings include various geometric mechanisms of quantum noise production and a noise-localization uncertainty relation. The methods involve Floer theory and Poisson bracket invariants originated in function theory on symplectic manifolds.

1.1 Registration procedure

For an open cover $\mathcal{U} = \{U_1, ..., U_L\}$ of a classical phase space M, the registration procedure yields an answer to the question *'Where (i.e. in which set U_i) is the system located?'* The ambiguity arising due to overlaps between the sets of the cover is resolved with the help of a partition of unity $f_1, ..., f_L$ subordinated to $\mathcal{U}$: every point $z \in M$ is registered in exactly one of the subsets U_i of the cover containing this point with probability $f_i(z)$.

The *Berezin-Toeplitz quantization* (which exists for all closed symplectic manifolds whose symplectic form represents an integral cohomology class) is given by a sequence of finite-dimensional complex Hilbert spaces H_m, $m \to \infty$ of increasing dimension and a family of $\mathbb{R}$-linear maps $T_m : C^\infty(M) \to \mathcal{L}(H_m)$ satisfying a number of axioms (most notably, the correspondence principle) which will be recalled later in Section 3.1. Here $\mathcal{L}(H_m)$ stands for the space of Hermitian operators on H_m. The number $\hbar = \frac{1}{m}$ represents the Planck constant, so that $m \to \infty$ is the classical limit. With this language, the quantum version of the registration procedure is defined by means of the sequence of POVMs

$$A^{(m)} = \{T_m(f_i)\} \tag{1}$$

on the finite space $\Omega_L = \{1, ..., L\}$. Being prepared in a pure state $[\xi] \in$

$\mathbb{P}(H_m)$, $|\xi| = 1$, the quantum system is registered in the set U_i with probability $\langle T_m(f_i)\xi, \xi \rangle$.

1.2 Inherent noise

The main character of our story is *the inherent noise* of POVMs coming from quantum registration procedures. This quantity, roughly speaking, measures the size of the non-random component of the quantum noise operator. The latter was studied earlier in [9, 30, 10, 23]. Let B be an $\mathcal{L}(H)$-valued POVM on a space Θ. We say that a POVM A on Ω_L is a smearing (or randomization) of B if there exists a measurable partition of unity $\{\gamma_j\}$ on Θ such as $A_j = \int_\Theta \gamma_j dB$ for all j. This equality can be interpreted as follows: every point $\theta \in \Theta$ diffuses into a point $j \in \Omega_L$ with probability $\gamma_j(\theta)$. To every random variable $x = (x_1, ..., x_L)$ on Ω_L corresponds a random variable $\Gamma x = \sum_j x_j \gamma_j$ on Θ which has the same operator valued expectation as x but whose operator valued variance

$$\Delta_B(\Gamma x) := \int_\Theta (\Gamma x)^2 \, dB - \Big(\int_\Theta \Gamma x \, dB \Big)^2$$

does not exceed the one of x (see inequality (8) below). *Is it possible to "derandomize" A in such a way that this variance is small for all $x \in [-1,1]^L$?* The obstruction to such a derandomization is given by the inherent noise of A which is defined as

$$\mathcal{N}_{in}(A) = \inf_B \max_{x \in [-1,1]^L} ||\Delta_B(\Gamma x)||_{op} ,$$

where the infimum is taken over all B such that A is a smearing of B. Here $|| \, ||_{op}$ stands for the operator norm.

A key feature of the inherent noise is as follows (see Section 3.3 below): Let $A^{(m)}$ be the sequence of POVMs (1) associated with the quantum registration procedure. Then there exists a constant $D > 0$ such that for all $m \in \mathbb{N}$

$$\mathcal{N}_{in}(A^{(m)}) \leq D \cdot \hbar , \tag{2}$$

where $\hbar = 1/m$. The main finding of the present paper is that for certain classes of covers the inherent noise satisfies lower bounds of the form $\mathcal{N}_{in}(A^{(m)}) \geq C \cdot \hbar$ for all sufficiently large m, where the constant C depends only on symplectic geometry and combinatorics of the covers. Our results can be briefly summarized as follows.

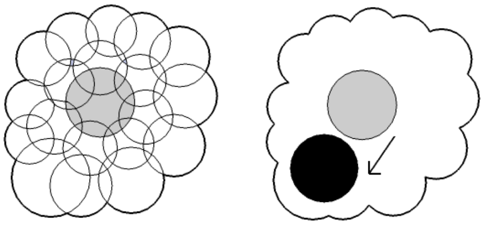

Figure 1: Displacement in two times iterated star

1.3 Noise-localization uncertainty relation

First, we discuss the principle stating that *'a sufficiently fine phase space localization yields the inherent quantum noise'*. Its qualitative version has been established in [32]. We present a quantitative version of this principle for the special class of open covers $\mathcal{U} = \{U_1, ..., U_L\}$ of M satisfying assumptions (R1) and (R2) below. Let us write $\overline{U}$ for the closure of a subset $U \subset M$.

R1. Every subset $\overline{U}_j$ intersects closures of at most d other subsets from the cover.

Further, for a subset $X \subset M$ define its *star* $St(X)$ as the union of all U_i's with $\overline{U}_i \cap \overline{X} \neq \emptyset$.

R2. For every i there exists a time-dependent Hamiltonian function $F_t^{(i)}$ on M, $t \in [0; 1]$ supported in the p times iterated star $St(...(St(U_i)...)$ of U_i such that the time one map ϕ_i of the corresponding Hamiltonian flow displaces U_i: $\phi_i(U_i) \cap \overline{U}_i = \emptyset$.

Assumption (R2) is illustrated in Figure 1. On the left one sees $p = 2$ times iterated star of the gray disc U_i, and on the right – its image (in black) under a Hamiltonian diffeomorphism ϕ_i represented by an arrow.

We call the covers satisfying (R1) and (R2) (d,p)*-regular*. We say that the *the magnitude of localization* of a (d,p)-regular cover $\mathcal{U}$ is $\leq \mathcal{A}$ if

$$\int_0^1 \max_M F_t^{(i)} - \min_M F_t^{(i)} \, dt \leq \mathcal{A} \quad \forall i = 1, ..., L \; .$$

In other words, we measure the size of subsets U_i in terms of their *displacement energy* (cf. [19, 31]), that is of minimal amount of energy required in order to displace U_i inside its p times iterated star. Let us mention that for certain d, p depending only on (M, ω) one has the following: for every sufficiently small $\mathcal{A} > 0$ there exists a (d,p)-regular cover with magnitude of localization $\leq \mathcal{A}$, see Example 4.5 below.

Given a (d,p)-regular cover $\mathcal{U}$, consider the sequence of POVMs $A^{(m)}$ given by (1). Our first result is the following *noise-localization uncertainty relation:*

Theorem 1.1.

$$\mathcal{N}_{in}(A^{(m)}) \cdot \mathcal{A} \geq C\hbar \quad \forall m \geq m_0 \; , \tag{3}$$

where the positive constant C *depends only on* d *and* p.

Let us note that number m_0 depends on the full data including the Berezin-Toeplitz quantization T and the partition of unity $\{f_j\}$. We refer the reader to Section 7.1 below for the proof of a more general version of this result and further discussion.

From a purely symplectic perspective, the noise-localization uncertainty relation is a manifistation of rigidity symplectic covers. Given a finite open cover $\mathcal{U} = \{U_1, ..., U_L\}$, we introduce the associated Poisson bracket invariant

$$pb(\mathcal{U}) = \inf_{\vec{f}} \max_{x,y \in [-1,1]^L} ||\{\sum x_i f_i, \sum y_j f_j\}|| \; ,$$

where the infimum is taken over all partitions of unity $\vec{f}$ subordinated to $\mathcal{U}$ formed by smooth functions $f_1, ..., f_L$. Here $\{.,.\}$ stands for the Poisson bracket and $||g|| = \max_M |g|$. This invariant serves as an obstruction to existence of a Poisson commutative partition of unity subordinated to $\mathcal{U}$. The study of lower bounds on pb and related invariants in terms of geometry of covers was initiated in [17] and has been continued in the PhD-thesis of Frol Zapolsky as well as in [32]. None of currently known bounds are

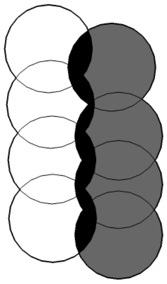

Figure 2: An overlap layer

sharp. For the applications to quantum mechanics we need the bounds which provide the sharp asymptotics in terms of the magnitude of localization of the cover. Such bounds will be given in Section 4 below. Their proof involves Floer-theoretical methods of function theory on symplectic manifolds. For instance, Theorem 1.1 will follow from the estimate $pb(\mathcal{U}) \geq C(p,d)\mathcal{A}^{-1}$ for every (d,p)-regular cover.

1.4 Overlap induced noise

Second, we present a different mechanism of the inherent quantum noise production based on geometry of overlaps. Given a finite open cover $\mathcal{U} = \{U_1, ..., U_L\}$ of M, consider any decomposition of the set $\{1, ..., L\}$ into disjoint union $I \sqcup I^c$ (upper index c stands for the complement) and define *an overlap layer* by $\Lambda(\mathcal{U}, I) := \bigcup_{\alpha \in I, \beta \in I^c} (U_\alpha \cap U_\beta)$. Observe that $M \setminus \Lambda(\mathcal{U}, I) = U(I) \sqcup U(I^c)$ where

$$U(I) := \Big(\bigcup_{\alpha \in I} U_\alpha \Big)^c .$$

We illustrate these notions on Fig. 2: Here the cover consists of discs. The discs U_α, $\alpha \in I$ form the left column, the discs U_β, $\beta \in I^c$ form the right column, and the corresponding overlap layer is colored in black. The sets $U(I)$ and $U(I^c)$ appear in gray (on the right) and in white (on the left) respectively.

Interestingly enough, the inherent quantum noise of a quantum registration procedure can be estimated in terms of quite subtle relative symplectic geometry of overlap layers of the corresponding cover . The main tool is the Poisson bracket invariant pb_4 introduced and studied in a recent paper [5] by means of Floer theory: Let X_0, X_1, Y_0, Y_1 be a quadruple of compact subsets of a symplectic manifold (M, ω) satisfying an intersection condition

$$X_0 \cap X_1 = Y_0 \cap Y_1 = \emptyset \; .$$

One of the equivalent definitions of pb_4 is as follows, see [5, Proposition 1.3]:

$$pb_4(X_0, X_1, Y_0, Y_1) = \inf ||\{f, g\}|| \; ,$$

where the infimum is taken over all pairs of functions $f, g : M \to [0; 1]$ with $f = 0$ near X_0, $f = 1$ near X_1, $g = 0$ near Y_0 and $g = 1$ near Y_1.

Given an open over $\mathcal{U}$ of M, consider the sequence of POVMs $A^{(m)}$ given by (1).

Theorem 1.2. *For every* $I, J \subset \Omega_L$

$$\mathcal{N}_{in}(A^{(m)}) \geq 2pb_4(U(I), U(I^c), U(J), U(J^c)) \cdot \hbar \tag{4}$$

for all sufficiently large m.

In Section 7.2 below we shall prove a more general version of this result in the context of joint measurements of POVMs corresponding to a pair of quantum registration procedures. It turns out that the POVMs associated to any pair of registration procedures admit a joint observable (see Proposition 3.4 below). We shall see that in certain examples geometry of overlaps enables us to detect inherent quantum noise of such a joint observable even in the absence of phase space localization.

As a case study, we explore overlap-induced noise for a pair of special covers of the unit sphere S^2 by annuli. We argue that a joint observable for POVMs associated to these covers is responsible for an approximate joint measurement of two components of spin. By using the technique of overlap layers, we get a lower bound for the inherent noise of such a measurement. Interestingly enough, it is related to the universal uncertainty relation for error bar widths of approximate joint measurements established earlier in [12, 26]. We refer to Sections 7.3 and 7.4 for further details.

Comparison with [32]: The study of quantum noise of POVMs associated to a quantum registration procedure via “hard” symplectic constraints on the Poisson brackets has been initiated in our recent paper [32]. For reader’s convenience, let us list the main new contributions of the present paper as compared with [32].

- We modify the measurement of non-random component of quantum noise by introducing inherent noise, which, in the context of quantum registration procedures, satisfies $C\hbar \leq \mathcal{N}_{in} \leq D\hbar$ in the classical limit $\hbar \to 0$ for some non-negative constants C, D. Thus the study of the value of the constant C (as opposed to the mere fact that $C > 0$ which was proved in [32]) becomes meaningful. This study eventually leads us to the noise-localization uncertainty relation (3) which is a manifestation of the qualitative principle “localization yields noise” established in [32].

- We find a new (as compared with [32]) mechanism of quantum noise production based on geometry of overlaps (see Theorem 1.2 above). In a somewhat unexpected twist, this mechanism turns out to be related to the Poisson bracket invariant pb_4 introduced earlier in [5] and studied there by means of various flavors of theory of pseudo-holomorphic curves in symplectic manifolds.

- Following a suggestion by Paul Busch [13] we extend our results to joint quantum measurements. In particular, *approximate* joint measurements (see Section 7 below) turn out to fit well the framework of quantum registration procedures.

Saying that, let us mention that we put an effort to make the present paper self-contained and hence there are inevitable overlaps with [32] as far as various preliminaries from operational quantum physics, the Berezin-Toeplitz quantization and symplectic geometry are concerned.

Organization of the paper: In Section 2 we remind preliminaries on POVMs and introduce the inherent quantum noise. The section is concluded with an unsharpness principle for POVMs and their joint observables which provides a lower bound on the inherent noise of a POVM in terms of its magnitude of non-commutativity.

In Section 3, after a brief reminder on the Berezin-Toeplitz quantization, we describe the classical registration procedure and its quantum counterpart.

Next we define *the noise indicator* which enables us discuss in a concise language inherent quantum noise of POVMs associated to quantum registration procedures. Finally, we introduce the Poisson bracket invariants of finite open covers of symplectic manifolds which provide lower bounds on the inherent quantum noise.

In Section 4 we study Poisson bracket invariants of fine open covers of symplectic manifolds. The highlight of this section is Theorem 4.8 providing lower bounds on the Poisson bracket invariants in terms of geometric and combinatorial properties of covers. The proofs involving methods of function theory on symplectic manifolds are presented in Section 5.

In Section 6 we detect the overlap induced noise by using pb_4-Poisson bracket invariant introduced in [5] (see Theorem 6.2).

In Section 7 we present various applications of our results to quantum mechanics: First, we state and prove the noise-localization uncertainty relation for a special class of fine open covers. Next, after discussing a link between the registration procedure and approximate quantum measurements, we detect the overlap induced noise for approximate measurements of two components of spin.

The paper is concluded with some open problems stated in Section 8.

2 Operational quantum mechanics

2.1 Preliminaries on POVMs

Let H be a complex Hilbert space. In the present paper we deal with finite-dimensional spaces only. Denote by $\mathcal{L}(H)$ the space of all Hermitian bounded operators on H. Consider a set Ω equipped with a σ-algebra $\mathcal{C}$ of its subsets. An $\mathcal{L}(H)$-valued *positive operator valued measure* A on $(\Omega, \mathcal{C})$ is a countably additive map $A : \mathcal{C} \to \mathcal{L}(H)$ which takes a subset $X \in \mathcal{C}$ to a positive operator $A(X) \in \mathcal{L}(H)$ and which is normalized by $A(\Omega) = \mathbb{1}$.

POVMs naturally appear in quantum measurement theory [8] where they play a role of generalized observables. The space Ω is called the *value space* of the observable. Pure states of the system are represented by the points of the projective space $[\xi] \in \mathbb{P}(H)$, where $\xi \in H$ is a unit vector. When the system is in a state $[\xi]$, the probability of finding the observable A in a subset $X \in \mathcal{C}$ is postulated to be $\langle A(X)\xi, \xi\rangle$.

An important class of POVMs is formed by *projection valued measures* for which all the operators $A(X)$, $X \in \mathcal{C}$ are orthogonal projectors. In the language of quantum measurement theory they are called *sharp* observables. Every "usual" von Neumann observable $B \in \mathcal{L}(H)$ corresponds to the projector valued measure $\widehat{B} = \sum P_j \delta_{\lambda_j}$ on $\mathbb{R}$, where $B = \sum_j \lambda_j P_j$ is the spectral decomposition of B. In this case the statistical postulate above agrees with the one of von Neumann's quantum mechanics.

When $\Omega = \Omega_L := \{1, ..., L\}$ is a finite set, any POVM A on Ω is fully determined by L positive Hermitian operators $A_i := A(\{i\})$ which sum up to $\mathbb{1}$.

2.2 Smearing of POVMs

Let Ω and Θ be Hausdorff locally compact second countable topological spaces. spaces and let $\mathcal{C}, \mathcal{D}$ be their Borel σ-algebras respectively. Denote by $\mathcal{P}(\Omega)$ the set of Borel probability measures on Ω. A *Markov kernel* is a map

$$\gamma : \Theta \to \mathcal{P}(\Omega),\ w \mapsto \gamma_w$$

such that the function $w \to \gamma_w(X)$ on Θ is measurable for every $X \in \mathcal{C}$. Let A and B be POVMs on $(\Omega, \mathcal{C})$ and $(\Theta, \mathcal{D})$ respectively. We say that A is a *smearing*[a] of B [8, 21, 1] if there exists a Markov kernel γ so that

$$A(X) = \int_\Theta \gamma_w(X)\, dB(w) \ \ \forall X \in \mathcal{C}\ .$$

In the physical language, each element w of the value set Θ of B diffuses into a subset $X \in \mathcal{C}$ with probability $\gamma_w(X)$.

Denote by $K(\Omega)$ the set of all measurable functions $x : \Omega \to \mathbb{R}$ with $\max |x| \leq 1$ which are interpreted as random variables on Ω. Every Markov kernel γ as above defines a *smearing operator*

$$\Gamma : K(\Omega) \to K(\Theta),\ (\Gamma x)(w) = \int_\Omega x\, d\gamma_w \ \ \forall w \in \Theta\ . \tag{5}$$

In the physical slang, the random variable Γx is a coarse-graining of x: Its value at a point $w \in \Theta$ is the expectation of x with respect to the measure γ_w.

---

[a] Some authors call it randomization or fuzzification.

For instance, if $\Omega = \Omega_N = \{1, ..., N\}$, a Markov kernel γ is given by a collection of non-negative measurable functions γ_j on Θ, $j = 1, ..., N$ so that $\sum_j \gamma_j(w) = 1$ for all $w \in \Theta$, that is by a measurable partition of unity. A POVM $A = \{A_1, ..., A_N\}$ on Ω_N,

$$A_j = \int_\Theta \gamma_j dB \ , \tag{6}$$

is a smearing of a POVM B on $(\Theta, \mathcal{D})$. Every function x from $K(\Omega_N)$ is canonically identified with a vector $x = (x(1), ..., x(N))$ lying in the cube $K_N := [-1, 1]^N$. The smearing operator Γ is given by $\Gamma(x) = \sum_j x_j \gamma_j$.

2.3 Quantum noise

Let $A : \mathcal{C} \to \mathcal{L}(H)$ be an $\mathcal{L}(H)$-valued POVM on $(\Omega, \mathcal{C})$. For a function $x \in K(\Omega)$ put $A(x) := \int x \, dA$ and define the noise operator

$$\Delta_A(x) = \int_\Omega x^2 dA - A(x)^2$$

(see [9, §2], [30, §4], [10, §3], [23, §2]). Roughly speaking, $A(x)$ is the operator valued expectation of the random variable x with respect to POVM A, while $\Delta_A(x)$ is its operator-valued variance.

Let us give a more precise interpretation of the noise operator (see e.g. [23]). Fix a quantum state $\xi \in H$, $|\xi| = 1$. Introduce the following pair of random variables, ϕ and ψ: Consider a measure σ_ξ on Ω given by $\sigma_\xi(X) = \langle A(X)\xi, \xi\rangle$. We define ϕ as $x : \Omega \to \mathbb{R}$, where Ω is equipped with the probability measure σ_ξ. The random variable ψ is associated to the von Neumann observable $A(x)$ and the state ξ: It takes values λ_j with probability $\langle P_j \xi, \xi\rangle$, where $A(x) = \sum \lambda_j P_j$ is the spectral decomposition. Both random variables have the same expectation $\langle A(x)\xi, \xi\rangle$, while the difference of their variances is given in terms of the noise operator:

$$\langle \Delta_A(x)\xi, \xi\rangle = \mathrm{Var}(\phi) - \mathrm{Var}(\psi) \ .$$

We refer to [23, 32] for the proof and a more detailed discussion.

The noise operator has a number of interesting properties, in particular $\Delta_A(x) \geq 0$. The equality $\Delta_A(x) = 0$ for all x corresponds precisely to the case when A is a projector valued measure.

Introduce the *magnitude of noise* $\mathcal{N}(A) := \max_{K(\Omega)} ||\Delta_A(x)||_{op}$, where $K(\Omega)$ is defined in the previous section and $||\ .||_{op}$ stands for the operator norm. The magnitude of noise is a dimensionless quantity satisfying (see [32])

$$0 \leq \mathcal{N}(A) \leq 1 \ . \tag{7}$$

Now we are ready to introduce one of the central notions of the present paper.

Definition 2.1. The *inherent noise* of a POVM A on $(\Omega, \mathcal{C})$ is given by

$$\mathcal{N}_{in}(A) := \inf_{B,\Gamma} \sup_{x \in K(\Omega)} ||\Delta_B(\Gamma x)||_{op} \ ,$$

where the infimum is taken over all POVMs B so that A is a smearing of B and Γ is the corresponding smearing operator.

Proposition 2.2. $\mathcal{N}_{in}(A) \leq \mathcal{N}(A)$.

Proof. By a result of Martens and de Muynck [24, Lemma 2, p.277]

$$\Delta_B(\Gamma x) \leq \Delta_A(x) \ , \tag{8}$$

where B is any smearing of A with the smearing operator Γ and x is any function from $K(\Omega)$. This immediately yields the proposition.

For the sake of completeness, let us prove inequality (8). Observe that $B(\Gamma x) = A(x)$. Furthermore, in the notation of Section 2.2, one calculates that

$$\int_\Omega x^2 \ dA - \int_\Theta (\Gamma x)^2 \ dB = \int_\Theta h(w) dB(w) \ ,$$

with

$$h(w) = \int_\Omega x^2 \ d\gamma_w - \Big(\int_\Omega x \ d\gamma_w \Big)^2 \ .$$

Since $h(w) \geq 0$ by the Cauchy-Schwarz inequality, we get (8). $\square$

Since smearing can be interpreted as a diffusion, the increment $\Delta_A(x) - \Delta_B(\Gamma x)$ (which is always non-negative by (8)) plays the role of a random component of the noise of A. That's why we call $\mathcal{N}_{in}(A)$ the *inherent* (as opposed to random) noise. Let us mention that in [32] a non-random component of the noise of A was measured in a slightly different way: we defined *a systematic* noise of a POVM A as $\inf_B \mathcal{N}(B)$ where the infimum is taken over all B so that A is a smearing of B. By definition, $||\Delta_B(\Gamma x)||_{op} \le \mathcal{N}(B)$, and hence $\mathcal{N}_{in}(A) \le \mathcal{N}_s(A)$. The inherent noise has a significant advantage in comparison with the systematic noise: In the context of quantum registration procedures, one can find an upper bound on $\mathcal{N}_{in}$ having the correct asymptotic behavior with respect to the quantum number (see Section 3.3 below), while the similar problem for $\mathcal{N}_s$ is at the moment out of reach. At the same time, both $\mathcal{N}_{in}$ and $\mathcal{N}_s$ obey an unsharpness principle which we are going to discuss in the next section.

It turns out that the inherent noise behaves monotonically under smearings.

Proposition 2.3. *$\mathcal{N}_{in}(A) \le \mathcal{N}_{in}(B)$ provided A is a smearing of B.*

Proof. Let us introduce the following notation: For a POVM A we write Ω^A for the value space of A and we abbreviate $K^A := K(\Omega^A)$. Following [24], we write $B \to A$ if A is a smearing of B, and denote by $\Gamma_{BA} : K^A \to K^B$ the smearing operator.

Observe that if $C \to B \to A$ we have that $\Gamma_{CA} = \Gamma_{CB}\Gamma_{BA}$. Therefore

$$\sup_{x\in K^A} ||\Delta_C(\Gamma_{CA}x)||_{op} = \sup_{x\in K^A} ||\Delta_C(\Gamma_{CB}\Gamma_{BA}x)||_{op} \le \sup_{y\in K^B} ||\Delta_C(\Gamma_{CB}y)||_{op} ,$$

and hence

$$\inf_{C\colon C\to B\to A} \sup_{x\in K^A} ||\Delta_C(\Gamma_{CA}x)||_{op} \le \inf_{C\colon C\to B} \sup_{y\in K^B} ||\Delta_C(\Gamma_{CB}y)||_{op} \le \mathcal{N}_{in}(B) .$$

Note that

$$\{C \ : \ C \to B \to A\} \subset \{C : C \to A\} .$$

Thus the left hand side of the last inequality is $\ge \mathcal{N}_{in}(A)$. We conclude that $\mathcal{N}_{in}(A) \le \mathcal{N}_{in}(B)$, as required. □

2.4 An unsharpness principle

For an $\mathcal{L}(H)$-valued POVM A on $(\Omega, \mathcal{C})$ define the magnitude of noncommutativity

$$\nu_q(A) = \sup_{x,y\in K(\Omega)} ||[A(x), A(y)]||_{op} , \tag{9}$$

where $[.,.]$ denotes the commutator and the subindex q stands for quantum.

Theorem 2.4 (Unsharpness principle)**.**

$$\mathcal{N}_{in}(A) \geq \frac{1}{2}\nu_q(A) \ . \tag{10}$$

Proof. Let B be an $\mathcal{L}(H)$-valued POVM on $(\Theta, \mathcal{D})$. By a lemma of Janssens (cf. [20], see also [25, 32])

$$||\Delta_B(u)||_{op}^{1/2} \cdot ||\Delta_B(v)||_{op}^{1/2} \geq \frac{1}{2} \cdot ||\ [B(u), B(v)]\ ||_{op} \tag{11}$$

for all $u, v \in K(\Theta)$.

Suppose now that an $\mathcal{L}(H)$-valued POVM A on $(\Omega, \mathcal{C})$ is a smearing of B with the smearing operator Γ. Take any $x, y \in K(\Omega)$ and substitue $u = \Gamma x$ and $v = \Gamma y$ into the above inequality. Since $B(u) = A(x)$ and $B(v) = A(y)$ we get that

$$||\Delta_B(\Gamma x)||_{op}^{1/2} \cdot ||\Delta_B(\Gamma y)||_{op}^{1/2} \geq \frac{1}{2} \cdot ||\ [A(x), A(y)]\ ||_{op} \ . \tag{12}$$

Therefore

$$\sup_x ||\Delta_B(\Gamma x)||_{op} \geq \frac{1}{2}\nu_q(A) \ ,$$

which yields the unsharpness principle. □

It is known [1, Section 5] (cf. [21]) that every commutative POVM on a Hausdorff locally compact second countable space is necessarily a smearing of a sharp observable, that is of a projector valued measure. In particular, $\mathcal{N}_{in}(A) = 0$ provided $\nu_q(A) = 0$. The unsharpness principle above shows that the converse statement is also true.

Let us mention also that the magnitude of non-commutativity behaves monotonically with respect to smearings (see [32]):

$$\nu_q(B) \geq \nu_q(A) \ \text{ if } \ A \ \text{ is a smearing of } \ B \ . \tag{13}$$

Thus after a smearing both sides of inequality (10) decrease.

2.5 An unsharpness principle for joint measurements

In this section we deal with POVMs defined on finite sets of the form $\Omega_L = \{1, ..., L\}$. Recall that two $\mathcal{L}(H)$-valued POVMs A and B on Ω_L and

Ω_N are *jointly measurable* [8] if there exists a POVM, say $C = \{C_{ij}\}$ on $\Omega := \Omega_L \times \Omega_N$ whose marginals equal A and B:

$$A_i = \sum_j C_{ij}, \;\; B_j = \sum_i C_{ij} \;\; \forall i \in \Omega_L, \; j \in \Omega_N \; .$$

Such a POVM C is called *a joint observable* for A and B. Let us emphasize that the question on joint measurability is a delicate one, and not every two POVMs admit a joint observable.

Given two POVMs A, B on Ω_L and Ω_N respectively, define the magnitude of (mutual) non-commutativity of A and B by

$$\nu_q(A, B) = \max_{x \in K_L, y \in K_N} ||[A(x), B(y)]||_{op} \; ,$$

where as earlier $A(x) := \sum x_i A_i$ and $K_L = [-1;1]^L$. With this notation, $\nu_q(A, A) = \nu_q(A)$, where the latter quantity is introduced in (9) above.

Proposition 2.5 (Unsharpness principle for joint measurements)**.** *Let C be a joint observable for $\mathcal{L}(H)$-valued POVMs A and B on Ω_L and Ω_N respectively Then*

$$\mathcal{N}_{in}(C) \geq \frac{1}{2} \cdot \max\Big(\nu_q(A), \nu_q(B), \nu_q(A, B)\Big) \; . \tag{14}$$

We refer to [25] for related results.

Proof. Indeed, take any $x \in K_L$, $y \in K_N$ and note that both $A(x)$ and $B(y)$ are linear combinations of C_{ij} with coefficients lying in $[-1;1]$. Thus $\nu_q(C) \geq \nu_q(A, B)$. Furthermore, A and B are smearings of C, and thus by (13) $\nu_q(C) \geq \nu_q(A)$ and $\nu_q(C) \geq \nu_q(B)$. Therefore

$$\nu_q(C) \geq \max\Big(\nu_q(A), \nu_q(B), \nu_q(A, B)\Big) \; ,$$

and so (14) follows from the unsharpness principle (10). ☐

3 Classical and quantum registration procedures

3.1 The Berezin-Toeplitz quantization

Recall that by the classical Darboux theorem, near each point of a symplectic manifold (M, ω) one can choose local coordinates $p_1, q_1, ..., p_n, q_n$ so that in these coordinates $\omega = \sum_{j=1}^{n} dp_j \wedge dq_j$. The space $C^\infty(M)$ of smooth functions on M is equipped with *the Poisson bracket* $\{f, g\}$, which in the Darboux coordinates (p, q) is given by

$$\{f, g\}(p, q) = \frac{\partial f}{\partial q} \cdot \frac{\partial g}{\partial p} - \frac{\partial f}{\partial p} \cdot \frac{\partial g}{\partial q} \ .$$

Let (M, ω) be a closed symplectic manifold whose symplectic form represents an integral de Rham cohomology class of M. In what follows such symplectic manifolds will be called *quantizable.* The Berezin-Toeplitz quantization [2, 3, 18, 4, 27, 34] consists of a sequence of finite-dimensional complex Hilbert spaces H_m, $m \to \infty$ of the increasing dimension and a family of surjective $\mathbb{R}$-linear maps $T_m : C^\infty(M) \to \mathcal{L}(H_m)$ with the following properties:

(BT1) $T_m(1) = 1\!\!1$;

(BT2) $T_m(f) \geq 0$ for $f \geq 0$;

(BT3) $||T_m(f)||_{op} = ||f|| + O(1/m)$;

(BT4) (*the correspondence principle*) $||i \cdot m[T_m(f), T_m(g)] - T_m(\{f, g\})||_{op} = O(1/m)$;

(BT5) $||T_m(f^2) - T_m(f)^2||_{op} = O(1/m)$,

as $m \to \infty$ for all $f, g \in C^\infty(M)$. Here $||f|| = \max |f(x)|$ stands for the uniform norm of a function $f \in C^\infty(M)$, $\{f, g\}$ for the Poisson bracket, $||A||_{op}$ for the operator norm of $A \in \mathcal{L}(H)$ and $[A, B]$ for the commutator $AB - BA$. The number m plays the role of the quantum number, while the Planck constant $\hbar$ equals $1/m$, so that $m \to \infty$ is the classical limit. As an immediate consequence of (BT3) and (BT4) we get that

$$\begin{aligned} ||m[T_m(f), T_m(g)]\ ||_{op} &= ||T_m(\{f, g\})||_{op} + O(1/m) \\ &= ||\{f, g\}|| + O(1/m) \end{aligned} \tag{15}$$

for all smooth functions f, g on M.

The Berezin-Toeplitz quantization can be described in the language of POVMs : There exists a sequence of $\mathcal{L}(H_m)$-valued POVMs G_m on the symplectic manifold M equipped with the Borel σ-algebra so that

$$T_m(f) = \int_M f \ dG_m \ . \tag{16}$$

This follows from Proposition 1.4.8 of Chapter II in [22] (the argument of [22] is repeated in [32]). Property (BT5) deserves a special discussion. Let $f, g \in C^\infty(M)$ be any two functions. Assume without loss of generality that $||f|| \leq 1$ and $||g|| \leq 1$. Then $\Delta_{G_m}(f) = T_m(f^2) - T_m(f)^2$ and hence by (11) and (15) above

$$\begin{aligned} ||T_m(f^2) - T_m(f)^2||_{op}^{1/2} \cdot ||T_m(g^2) - T_m(g)^2||_{op}^{1/2} \\ \geq \frac{1}{2} \cdot ||[T_m(f), T_m(g)]||_{op} = ||\{f,g\}||/(2m) + O(1/m^2) \ . \quad (17) \end{aligned}$$

Assume now that the function f is non-constant. Then there exists a function g with $\{f, g\} \neq 0$, and we conclude that $T_m(f^2) \neq T_m(f)^2$ for all sufficiently large m.

3.2 Registration

Let (M, ω) be a closed connected symplectic manifold playing the role of the phase space of a classical system. Take a finite open cover $\mathcal{U} = \{U_1, ..., U_L\}$ of M. A partition of unity $\vec{f} = \{f_1, ..., f_L\}$ subordinated to $\mathcal{U}$ is a collection of smooth non-negative real-valued functions f_i on M with $\text{supp}(f_i) \subset U_i$ and $f_1 + ... + f_L = 1$. Here $\text{supp}(f)$ stands for the support of the function f, that is for the closure of the set $\{f \neq 0\}$. Such partitions of unity naturally appear in the following *registration procedure* [32]: every point $z \in M$ is registered with probability $f_i(z)$ in exactly one of the subsets U_i of the cover containing this point. This procedure can be considered as an attempt of phase space localization of the classical system with respect to the cover $\mathcal{U}$: It yields an answer to the question *'Where (i.e. in which set U_j) is the system located?'*

Example 3.1. Fix a Riemannian metric on M and a number $r > 0$ which is sufficiently small in comparison with the injectivity radius of M. Let ρ be the correspondent distance function. For a point $z \in M$ denote by $D(z, r)$ the open metric ball of radius r centered at z. A (necessarily, finite) collection of distinct points $\{z_1, ..., z_L\}$ in M is called $r/2$-*separated* (cf. [6]) if $\rho(z_i, z_j) \geq r/2$ for all $i \neq j$. Take any $r/2$-separated collection and add points to it keeping it $r/2$-separated until the process terminates. The resulting collection, say, Z is *maximal*: there is no $r/2$-separated collection containing it as a proper subset. In other words, every point $z \in M$ lies at distance

$< r/2$ from some $z_j \in Z$. Therefore the balls $D(z, r/2)$, $z \in Z$ cover M. We call the cover $\{D(z,r)\}$, $z \in Z$ *greedy* (by technical reasons, it is convenient to deal with balls of radius r as opposed to $r/2$). The corresponding registration problem reflects a naive attempt of phase space discretization.

Example 3.2. Take a smooth function $F : M \to \mathbb{R}$. Consider the closed interval $I := [\min F, \max F]$. Let $\{W_i\}$ be a cover of I by open intervals of length $< c$, and let $\{h_i\}$ be smooth functions $\mathbb{R} \to [0,1]$ so that $\sum h_i = 1$ on I and each h_i is supported in W_i. Then the functions $h_i \circ F$ form a partition of unity subordinated to the open cover $\{F^{-1}(W_i)\}$ of M. The outcome of the corresponding registration procedure can be spelled out as follows: the value of F at a given point $z \in M$ lies in the interval W_i with the probability $p_i = h_i(F(z))$. Thus the registration procedure yields an approximation to the genuine value $F(z)$ with the error c. This example will serve as a starting point of our discussion on approximate measurements in Section 7.3 below.

In order to describe a quantum counterpart of the registration procedure, fix a scheme T_m of the Berezin-Toeplitz quantization. It takes the partition of unity $\{f_i\}$ to an $\mathcal{L}(H_m)$-valued POVM $A^{(m)}$ on the finite set $\Omega_L = \{1, ..., L\}$, where $A_i^{(m)} := T_m(f_i)$. Being prepared in a pure state $[\xi] \in \mathbb{P}(H_m)$, $|\xi| = 1$, the quantum system is registered in the set U_i with probability $\langle T_m(f_i)\xi, \xi\rangle$.

3.3 The noise indicator: a single partition of unity

Fix a scheme of the Berezin-Toeplitz quantization $T_m : C^\infty(M) \to \mathcal{L}(H_m)$. For a partition of unity $\vec{f} = \{f_i\}$, $i = 1, ..., L$ of M consider the POVM $A^{(m)} = \{T_m(f_j\}$ and focus on the sequence of non-negative numbers $m \cdot \mathcal{N}_{in}(\{T_m(f_i)\}$, $m \geq 0$, where $\mathcal{N}_{in}$ stands for the inherent noise. First of all we claim that this sequence is necessarily bounded from above (this justifies inequality (2) from the introduction). Indeed, observe that $A^{(m)}$ is a smearing of the Berezin-Toeplitz POVM G_m, where the smearing operator is given by the partition of unity:

$$\Gamma x = \sum_i x_i f_i$$

for every $x \in K_L = [-1,1]^L$. The noise operator can be written as

$$\Delta_{G_m}(\Gamma x) = T_m((\Gamma x)^2) - T_m(\Gamma x)^2 \; .$$

Since the functions Γx, $x \in K_L = [-1,1]^L$ form a compact subset in C^∞-topology, the property (BT5) of the Berezin-Toeplitz quantization yields the bound

$$\sup_{x \in K_L} ||\Delta_{G_m}(\Gamma x)||_{op} \leq D/m$$

for some $D > 0$. By definition, the left hand side of this inequality is $\geq \mathcal{N}_{in}(A^{(m)})$, and hence $m \cdot \mathcal{N}_{in}(\{T_m(f_i)\}) \leq D$. The claim follows. Therefore, the quantity $\mu_T(\vec{f}) := \liminf_{m \to \infty} m \cdot \mathcal{N}_{in}(\{T_m(f_i)\})$ is necessarily finite. Now we are ready to define one of the central notions of the present paper.

Definition 3.3. Let $\mathcal{U} = \{U_1, ..., U_L\}$ be a finite open cover of a closed quantizable symplectic manifold (M, ω). The *noise indicator* of $\mathcal{U}$ is defined as

$$\mu(\mathcal{U}) := \inf_{\vec{f}, T} \mu_T(\vec{f}) \ ,$$

where the infimum is taken over all partitions of unity $\vec{f}$ subordinated to $\mathcal{U}$ and over all schemes T_m of the Berezin-Toeplitz quantization.

3.4 The noise indicator: joint measurements

Consider POVMs $A^{(m)} = \{T_m(f_i)\}$ and $B^{(m)} = \{T_m(g_j)\}$, where $\vec{f} = \{f_i\}$ and $\vec{g} = \{g_j\}$ are partitions of unity on M.

Proposition 3.4. *POVMs $A^{(m)}$ and $B^{(m)}$ necessarily admit a joint observable on $\Omega := \Omega_L \times \Omega_N$.*

Let us emphasize that a joint observable is not unique and does not necessarily has a classical counterpart.

Proof. Put $D_{ij}^{(m)} := T_m(f_i g_j)$. Note that since $f_i g_j \geq 0$ these operators are positive. Since $\sum f_i g_j = 1$ and T_m is linear with $T_m(1) = \mathbb{1}$, these operators sum up to $\mathbb{1}$. Thus $\{D_{ij}^{(m)}\}$ form a POVM, say $D^{(m)}$ on Ω. Let us check that its marginals are precisely $A^{(m)}$ and $B^{(m)}$. Indeed, since $\sum_i f_i g_j = g_j$ we get (again by linearity of T_m) that

$$\sum_i D_{ij}^{(m)} = T_m(g_j) = B_j^{(m)} \ ,$$

and similarly for $A^{(m)}$. □

Let

$$\mu_T(\vec{f},\vec{g}) = \inf_{C^{(m)}} \liminf_{m\to\infty} m \cdot \mathcal{N}_{in}(C^{(m)}) \ ,$$

where the infimum is taken over all joint observables $C^{(m)}$ of $A^{(m)}$ and $B^{(m)}$. Put $\vec{f}\cdot\vec{g} := \{f_i g_j\}$. Since $\{T_m(f_i g_j)\}$ provides such a joint observable, $\mu_T(\vec{f},\vec{g}) \leq \mu_T(\vec{f}\cdot\vec{g}) < \infty$.

Definition 3.5. Let $\mathcal{U} = \{U_1, ..., U_L\}$ and $\mathcal{V} = \{V_1, ..., V_N\}$ be a pair of finite open covers of a closed quantizable symplectic manifold (M,ω). The *noise indicator* of the pair $\mathcal{U},\mathcal{V}$ is defined as

$$\mu(\mathcal{U},\mathcal{V}) := \inf_{\vec{f},\vec{g},T} \mu_T(\vec{f},\vec{g}) \ ,$$

where the infimum is taken over all partitions of unity $\vec{f}$ and $\vec{g}$ subordinated to $\mathcal{U}$ and $\mathcal{V}$ respectively and over all schemes T_m of the Berezin-Toeplitz quantization.

Observe that the POVM $A_{ij} = A_i \cdot \delta_{ij}$, where δ_{ij} is the Kronecker delta, is a joint observable for two copies of a POVM $A = \{A_i\}$. Therefore

$$\mu(\mathcal{U},\mathcal{U}) \leq \mu(\mathcal{U}) \ . \tag{18}$$

3.5 The Poisson bracket invariants

The objective of the present paper is to find lower bounds on the noise indicators in terms of symplectic geometry and topology of the covers. The first step in this direction is provided by the correspondence principle (BT4).

For a partition of unity $\vec{f} = \{f_i\}$, $i = 1, ..., L$ introduce the magnitude of its Poisson non-commutativity

$$\nu_c(\vec{f}) := \max_{x\in K_L, y\in K_L} ||\{\sum_i x_i f_i, \sum_i y_i f_i\}|| \ ,$$

where as above K_L stands for the cube $[-1;1]^L \subset \mathbb{R}^L$ (cf. (9) above; the subindex c stands for classical). Given an open cover $\mathcal{U} = \{U_1, ..., U_L\}$ of M, define the Poisson bracket invariant $pb(\mathcal{U}) = \inf \nu_c(\vec{f})$, where the infimum is taken over all partitions of unity $\vec{f}$ subordinated to $\mathcal{U}$.

Similarly, given a pair of partitions of unity $\vec{f} = \{f_i\}$, $i = 1, ..., L$ and $\vec{g} = \{g_j\}$, $j = 1, ..., N$, put

$$\nu_c(\vec{f}, \vec{g}) := \max_{x \in K_L, y \in K_N} ||\{\sum_i x_i f_i, \sum_j y_j g_j\}|| \; .$$

Introduce the Poisson bracket invariant of two open covers $\mathcal{U}$ and $\mathcal{V}$:

$$pb(\mathcal{U}, \mathcal{V}) = \inf_{\vec{f}, \vec{g}} \max \Big(\nu_c(\vec{f}), \nu_c(\vec{g}), \nu_c(\vec{f}, \vec{g}) \Big) \; , \tag{19}$$

where the infimum is taken over all partitions of unity subordinated to our covers.
Note that $pb(\mathcal{U}, \mathcal{V}) \geq \max(pb(\mathcal{U}), pb(\mathcal{V}))$. On the other hand, taking $\vec{f} = \vec{g}$ in the above definition, we get that $pb(\mathcal{U}, \mathcal{U}) \leq pb(\mathcal{U})$. Therefore

$$pb(\mathcal{U}, \mathcal{U}) = pb(\mathcal{U}) \; . \tag{20}$$

The next result, which provides a lower bound on the noise indicator in terms of the Poisson bracket invariants, serves as a bridge between quantum measurements and symplectic geometry.

Theorem 3.6. *(i) For every finite open cover $\mathcal{U}$ of M*

$$\mu(\mathcal{U}) \geq \frac{1}{2} \cdot pb(\mathcal{U}) \; . \tag{21}$$

(ii) For every pair of finite open covers $\mathcal{U}$ and $\mathcal{V}$ of M

$$\mu(\mathcal{U}, \mathcal{V}) \geq \frac{1}{2} \cdot pb(\mathcal{U}, \mathcal{V}) \; . \tag{22}$$

Proof. We shall proof (22) (the proof is (21) is completely analogous). Let $\mathcal{U}$ and $\mathcal{V}$ be a pair of open covers of a closed symplectic manifold (M, ω). Let $\vec{f} = \{f_i\}$, $\vec{g} = \{g_j\}$ be any partitions of unity subordinated to $\mathcal{U}$ and $\mathcal{V}$ respectively. Let $C^{(m)}$ be any $\mathcal{L}(H_m)$-valued POVM providing a joint measurement for $A^{(m)} = \{T_m(f_i)\}$ and $B^{(m)} = \{T_m(g_j)\}$. If $pb(\mathcal{U}, \mathcal{V}) = 0$, (22) follows automatically. Otherwise, take any positive number $p < pb(\mathcal{U}, \mathcal{V})$. Observe that by (15)

$$\max \Big(\nu_q(A^{(m)}), \nu_q(B^{(m)}), \nu_q(A^{(m)}, B^{(m)}) \Big)$$

$$= \frac{1}{m} \cdot \max(\nu_c(\vec{f}), \nu_c(\vec{g}), \nu_c(\vec{f}, \vec{g})) + O(1/m^2) \geq p/m$$

for all sufficiently large m. Hence $\mathcal{N}_{in}(C^{(m)}) \geq p/(2m)$ for all sufficiently large m by unsharpness principle (14). ☐

4 Poisson bracket invariants of fine covers

4.1 Basic properties of the Poisson bracket invariants

Recall that Ω_L stands for the finite set $\{1, ..., L\}$. Let $\mathcal{U} = \{U_1, ..., U_L\}$ and $\mathcal{W} = \{W_1, ..., W_K\}$ be two open covers of M. The cover $\mathcal{W}$ is called a *refinement* of $\mathcal{U}$ if there exists a map $\phi : \Omega_K \to \Omega_L$ such that $W_i \subset U_{\phi(i)}$ for all $i \in \Omega_K$.

Proposition 4.1. *$pb(\mathcal{U}) \leq pb(\mathcal{W})$ whenever $\mathcal{W}$ is a refinement of U.*

Proof. Let $\vec{g} = \{g_1, ..., g_K\}$ be any partition of unity subordinated to $\mathcal{W}$. For $l \in \Omega_L$ put

$$f_l = \sum_{i \in \phi^{-1}(l)} g_i \ .$$

The collection of functions $\vec{f} = \{f_l\}$ is a partition of unity subordinated to $\mathcal{U}$. Further, given $x \in K_L = [-1, 1]^L$, the function $\sum x_l f_l$ is a linear combination of g_i's with coefficients from $[-1, 1]$. Thus $\nu_c(\vec{f}) \leq \nu_c(\vec{g})$. Since $pb(\mathcal{U}) \leq \nu_c(\vec{f})$, we get that $pb(\mathcal{U}) \leq \nu_c(\vec{g})$ for every $\vec{g}$. Therefore $pb(\mathcal{U}) \leq pb(\mathcal{W})$. ☐

For two open covers $\mathcal{U}$ and $\mathcal{V}$ denote by $\mathcal{U} \cdot \mathcal{V}$ the cover $\{U_i \cap V_j\}$.

Proposition 4.2.

$$\max(pb(\mathcal{U}), pb(\mathcal{V})) \leq pb(\mathcal{U} \cdot \mathcal{V}) \leq 4pb(\mathcal{U}, \mathcal{V}) \ .$$

Proof. The inequality on the left immediately follows from Proposition 4.1. Let us prove the inequality on the right.

Take any partitions of unity $\vec{f} = \{f_i\}$ and $\vec{g} = \{g_j\}$ subordinated to coverings $\mathcal{U}$ and $\mathcal{V}$ respectively. Put

$$a := \max\left(\nu_c(\vec{f}), \nu_c(\vec{g}), \nu_c(\vec{f}, \vec{g})\right) \ .$$

Look at the partition of unity $\vec{f}\cdot\vec{g} = \{f_i g_j\}$ subordinated to the cover $\{U_i \cap V_j\}$ of M. Note that

$$\{f_i g_j, f_k g_l\} = f_i f_k \{g_j, g_l\} + g_j g_l \{f_i, f_k\} + f_i g_l \{g_j, f_k\} + g_j f_k \{f_i, g_l\} \ . \quad (23)$$

Choose arbitrary weights x_{ij} and y_{kl} in $[-1; 1]$. Put

$$F_j^x = \sum_i x_{ij} f_i \ , F_l^y = \sum_k y_{kl} f_k \ , G_i^x = \sum_j x_{ij} g_j \ , G_k^y = \sum_l y_{kl} g_l \ .$$

Fix a point $z \in M$ and put

$$I(z) = \Big| \Big\{ \sum_{i,j} x_{ij} f_i g_j, \sum_{k,l} y_{kl} f_k g_l \Big\}(z) \Big| \ .$$

Calculating with the help of (23) and estimating, we get that

$$I(z) \leq I_1(z) + I_2(z) + I_3(z) + I_4(z) \ ,$$

where

$$I_1(z) = \sum_{i,k} f_i(z) f_k(z) |\{G_i^x, G_k^y\}(z)| \ \ , \ \ I_2(z) = \sum_{j,l} g_j(z) g_l(z) |\{F_j^x, F_l^y\}(z)| \ ,$$

$$I_3(z) = \sum_{i,l} f_i(z) g_l(z) |\{G_i^x, F_l^y\}(z)| \ \ , \ \ I_4(z) = \sum_{j,k} g_j(z) f_k(z) |\{F_j^x, G_k^y\}(z)| \ .$$

Observe that

$$|\{G_i^x, G_k^y\}(z)| \leq \nu_c(\{g_j\}) \leq a \ .$$

Thus

$$I_1(z) \leq a \cdot \sum_{i,k} f_i(z) f_k(z) = a \cdot \sum_i f_i(z) \cdot \sum_k f_k(z) = a \ .$$

Similarly, $I_\alpha(z) \leq a$ for $\alpha = 2, 3, 4$ and hence $I(z) \leq 4a$. Therefore

$$\nu_c(\vec{f} \cdot \vec{g}) \leq 4a \ .$$

This yields $pb(\mathcal{U} \cdot \mathcal{V}) \leq 4pb(\mathcal{U}, \mathcal{V})$, as required. □

4.2 Small scales in symplectic geometry

Recall that a *Hamiltonian diffeomorphism* is a time one map ϕ_H of a Hamiltonian flow on M generated by a (in general, time dependent) Hamiltonian $H(z,t)$ on M. Hamiltonian diffeomorphisms form a group denoted by $Ham\,(M)$. Given a Hamiltonian diffeomorphism $\phi \in Ham\,(M)$, define its Hofer's norm [19] by

$$||\phi||_{Hofer} = \inf_{H\,:\,\phi_H=\phi} \int_0^1 \Big(\max_z H(z,t) - \min_z H(z,t) \Big) \cdot dt \ .$$

Here the infimum is taken over all Hamiltonians H generating ϕ, and hence Hofer's norm of ϕ measures the minimal possible amount of energy required in order to generate ϕ.

A subset $Z \subset M$ is called *displaceable* if there exists a Hamiltonian diffeomorphism ϕ of M so that

$$\phi(Z) \cap \text{Closure}(Z) = \emptyset. \tag{24}$$

For a displaceable subset Z define its *displacement energy*

$$E(Z) = \inf ||\phi||_{Hofer} \ ,$$

where the infimum is taken over all $\phi \in Ham\,(M)$ satisfying (24). We put $E(Z) = \infty$ if Z is non-displaceable. We refer to [31] for an introduction to Hofer's geometry. The sets of displacement energy $\leq r$, $r \to 0$ provide a natural family of small scales in symplectic geometry.

In what follows, we shall need also relative versions of the above notions. Let $U \subset M$ be an open subset. Denote by $Ham\,(U)$ the subgroup of $Ham\,(M)$ generated by Hamiltonian diffeomorphisms $H(z,t)$ supported in $U \times [0;1]$. We say that $Z \subset U$ is *displaceable in* U if (24) holds for some $\phi \in Ham\,(U)$, and we define the *relative displacement energy* $E(Z,U)$ as the infimum of Hofer's norms of such ϕ.

4.3 Liouville domains

The following class of subsets will play an important role below. Let $\overline{U} \subset M^{2n}$ be a closed $2n$-dimensional submanifold with the interior U and the boundary ∂U.

Topological assumption: In what follows we assume that all connected components of $\overline{U}$ are simply connected. Let us emphasize that $\overline{U}$ is not assumed to be connected.

We say that $\overline{U}$ (resp. U) is *a closed (resp. open) Liouville domain* [15] if there exists a vector field ξ on $\overline{U}$ which is transversal to the boundary ∂U and which satisfies $L_\xi \omega = \omega$, where L stands for the Lie derivative. The vector field ξ is called a Liouville vector field.

Note that at the boundary the field ξ points outward. Therefore the flow $R_\tau : \overline{U} \to \overline{U}$ of ξ is well defined for all non-positive times $\tau \leq 0$. This flow dilates the symplectic form: $R_\tau^* \omega = e^\tau \omega$.

Let ξ and η be two Liouville vector fields, and R_τ, T_τ, $\tau \leq 0$ be their flows. Fix $\tau < 0$ and put $V = R_\tau(\overline{U})$ and $W = T_\tau(\overline{U})$. Observe that $T_{-t}(R_{-t})^{-1}(V)$, $t \in [0, -\tau]$ is a symplectic isotopy which takes V to W. Since all connected components of $\overline{U}$ are simply connected, this isotopy is Hamiltonian. By the Hamiltonian isotopy extension theorem, this isotopy extends to a Hamiltonian diffeomorphism of U. Since the displacement energy is invariant under Hamiltonian diffeomorphisms, the quantity $E(R_t U, U)$ does not depend on the specific choice of the Liouville field ξ.

In what follows it will be useful to rescale the variable τ and to adopt the following notation: For $s \in (0, 1]$ put $sU = R_{\log s}(U)$.

Observe that $s_1 U \subset s_2 U$ for $s_1 < s_2$. The closed set $Q := \bigcap_{s \in (0,1]} sU$ is called *the core* of U. We say that the Liouville domain is *portable* (cf. [7]) if Q is displaceable in U.

For a portable Liouville domain U define a function $F_U(s) = E(sU, U)/s$. It is defined on $(0, 1]$ and takes values in $(0, +\infty]$. By the discussion above, F_U is independent on the Liouville vector field.

Observe that $F_U(s)$ is finite for $s < s_0$ for some $s_0 > 0$. Further, $E(stU, U) \leq E(stU, tU) = tE(sU, U)$, where the inequality follows from the definitions, and the equality from the fact that the pair (U, sU) is conformally symplectomorphic to (tU, stU). Dividing by st, we get that $F_U(s)$ is non-decreasing on $(0, s_0]$. Define the *portability number* of U by

$$\chi(U, \omega) = \inf F_U = \lim_{s \to 0} F_U(s) \ . \tag{25}$$

Let us emphasize that the portability number is an intrinsic invariant of (U, ω): it does not depend on the symplectic embedding $U \to M$. We put $\chi(U, \omega) = \infty$ if U is not portable and abbreviate $\chi(U)$ when the symplectic form ω is clear from the context.

Example 4.3. Let $B^{2n}(r)$ be a closed Euclidean ball of radius r centered at 0 in the linear symplectic space $(\mathbb{R}^{2n}, dp \wedge dq)$. This is a Liouville domain with the Liouville vector field $\xi = (p\partial/\partial p + q\partial/\partial q)/2$. Its core coincides with the origin, and hence U is portable. Observe that in our notations $sB^{2n}(r) = B^{2n}(r\sqrt{s})$. For s small enough, the displacement energy of $B^{2n}(r\sqrt{s})$ in $B^{2n}(r)$ equals $\pi(r\sqrt{s})^2$ [28] and hence $\chi(B^{2n}(r)) = \pi r^2$.

Example 4.4. More generally, every star-shaped bounded domain with smooth boundary in $\mathbb{R}^{2n}$ is portable Liouville. This yields that given a closed symplectic manifold (M, ω) equipped with a Riemannian metric, all metric balls of a sufficiently small radius are portable Liouville.

Observe that the disjoint union of two closed Liouville domains is again a closed Liouville domain. The following property of the portability number will be useful for our purposes. Let $\overline{U}$ and $\overline{V}$ be a pair of disjoint closed Liouville domains. Since $F_{U \sqcup V} = \max(F_U, F_V)$,

$$\chi(U \sqcup V) = \max(\chi(U), \chi(V)) \; . \tag{26}$$

4.4 Main theorems on fine regular covers

We write $\overline{U}$ for the closure of a subset U. Let $\mathcal{U} = \{U_1, ..., U_L\}$ be an open cover of a closed symplectic manifold (M, ω). We say that *the degree* of $\mathcal{U}$ is $\leq d$ if every subset $\overline{U}_j$ intersects closures of at most d other subsets from the cover. For a subset $X \subset M$ define its *star* $St(X)$ as the union of all U_i's with $\overline{U}_i \cap \overline{X} \neq \emptyset$. The p times iterated star (for brevity, p-star) $St(...(St(X)...)$ is denoted by $St_p(X)$. Put

$$E_p(\mathcal{U}) = \max_i E(U_i, St_p(U_i)) \; .$$

We say that the cover $\mathcal{U}$ is (d,p)*-regular* if the degree of $\mathcal{U}$ is $\leq d$ and $E_p(\mathcal{U}) < \infty$. The latter condition means that every subset U_j is displaceable in its p-star. Let us emphasize that the notion of (d,p)-regularity and as well as the quantity E_p is invariant under symplectomorphisms of M.

Example 4.5. Let $\mathcal{U}$ be a greedy cover responsible for the phase space discretization into Riemannian balls of radius r, see Example 3.1 above. For all $0 < r \leq r_0$ this cover is (d,p)-regular with $E_p(\mathcal{U}) \leq \kappa r^2$, where the constants r_0, d, p and κ depend only on the symplectic manifold (M, ω) and the Riemannian metric ρ. The proof will be given in Section 4.6.

The moral of this example is that for some positive integers d, p the following holds true: for every $\epsilon > 0$ every finite open cover $\mathcal{V}$ of M admits a (d,p)-regular refinement with $E_p < \epsilon$. In view of this we shall refer to $E_p(\mathcal{U})$ as to the magnitude of localization of $\mathcal{U}$. The magnitude of localization could be arbitrarily small while the parameters d, p remain bounded.

An important property of (d,p)-regular covers is as follows.

Proposition 4.6. *Every (d,p)-regular cover $\mathcal{U}$ is a refinement of a cover $\mathcal{W} = \{W_1, ..., W_N\}$ where N depends only on d, p and $E(W_j) \leq E_p(\mathcal{U})$ for all j.*

Let us pass now to fine open covers $\mathcal{U}$ by portable Liouville domains. In this case we keep track of the degree of the cover and measure the magnitude of localization with the help of the quantity $\chi(\mathcal{U}) := \max_j \chi(U_j)$. Again, greedy covers of a sufficiently small radius provide an example of a Liouville cover of bounded degree with an arbitrary small magnitude of localization (see Example 4.4 above).

Proposition 4.7. *Every degree $\leq d$ cover $\mathcal{U}$ by portable Liouville domains is a refinement of a cover $\mathcal{W} = \{W_1, ..., W_N\}$ by portable Liouville domains, where $N \leq d+1$ and $\chi(\mathcal{U}) = \chi(\mathcal{W})$.*

The main result of the present section is as follows:

Theorem 4.8. *Let $\mathcal{W} = \{W_1, ..., W_N\}$ be an open cover of a closed symplectic manifold (M, ω). Assume that*

(i) either all subsets W_j are displaceable with $E(W_j) \leq \mathcal{A}$.

(ii) or $\pi_2(M) = 0$, and all subsets W_j are Liouville with $\chi(W_j) \leq \mathcal{A}$. Then

$$pb(\mathcal{W}) \geq C(N)\mathcal{A}^{-1} , \tag{27}$$

where the constant $C(N)$ depends only on N.

In (ii) $\pi_2(M)$ stands for the second homotopy group of M. The condition $\pi_2(M) = 0$ means the every sphere in M contracts to a point. It holds, for instance, when M is the $2n$-dimensional torus. This condition cannot be lifted: one can show that Theorem (4.8)(ii) is wrong as stated for the sphere S^2. It would be interesting to explore whether the statement could be modified so that it will hold for all closed symplectic manifolds.

In view of Propositions 4.6 and 4.7 we get that for a (d,p)-regular cover (resp., a Liouville cover of degree $\leq d$) with the magnitude of localization $\mathcal{A}$

$$pb(\mathcal{U}) \geq C \cdot \mathcal{A}^{-1} , \tag{28}$$

where the constant C depends only on d, p (resp. only on d). By Proposition 4.1 the same inequality holds for refinements of these covers.

4.5 Combinatorics of covers

Our next goal is to prove Propositions 4.6 and 4.7. It would be convenient to introduce the following combinatorial language. Let $\mathcal{U} = \{U_1, ..., U_L\}$ be an open cover of a closed manifold M. Define the graph Υ whose vertices form the set $\Omega_L = \{1, ..., L\}$. Vertices i and j are joined by an edge if and only if $\overline{U}_i \cap \overline{U}_j \neq \emptyset$. Let γ be the graph metric on Υ: the distance between two vertices is defined as the number of edges in the shortest path connecting them. Denote by $d(\mathcal{U})$ the maximal degree of a vertex in Υ.

Recall that the chromatic number of a graph is the smallest number of colors needed to color the vertices so that no two adjacent vertices share the same color. It is well known that the chromatic number does not exceed $d+1$ where d is the maximal vertex degree of the graph.

Proposition 4.9. *For every $k \in \mathbb{N}$ the vertices of Υ can be colored into $\leq d(\mathcal{U})^k + 1$ colors in such a way that every two vertices of the same color lie at the distance $\geq k+1$.*

Proof. Denote by Υ^k a graph whose vertices coincides with the ones of Υ, and where two vertices are connected by an edge if and only if the distance between them is $\leq k$. Clearly, the maximal degree of a vertex in Υ^k does not exceed $a := d(\mathcal{U})^k$. Therefore its chromatic number does not exceed $a+1$. By definition, this means that Υ^k can be colored in $\leq a+1$ colors so that any two vertices i, j of the same color are not connected by an edge in Υ^k. This means the $\gamma(i,j) \geq k+1$. □

Proof of Proposition 4.6: Let $\mathcal{U} = \{U_1, ..., U_L\}$ be a (d,p)-regular open cover of M. By Proposition 4.9 the sets U_j can be colored in $N \leq d^{2p} + 1$

colors so that for every two sets U_i and U_j of the same color the stars $St_p(U_i)$ and $St_p(U_j)$ do not intersect. For $\alpha \in \{1, ..., N\}$ denote by I_α the set of all indices i such that U_i is of color α. Put $W_\alpha = \sqcup_{i \in I_\alpha} U_i$. The cover $\mathcal{U}$ is a refinement of $\{W_\alpha\}$. Since for all $i \in I_\alpha$ the set U_i is displaceable in $St_p(U_i)$ and the stars $St_p(U_i)$ are pairwise disjoint,

$$E(W_\alpha) \leq E(\sqcup_{i \in I_\alpha} U_i, \sqcup_{i \in I_\alpha} St_p(U_i)) =$$

$$\max_{i \in I_\alpha} E(U_i, St_p(U_i)) \leq E_p(\mathcal{U}) \ .$$

This completes the proof. □

Proof of Proposition 4.7: Let $\mathcal{U} = \{U_1, ..., U_L\}$ be a d-regular finite open cover of M so that all subsets U_j are open portable Liouville domains. The elements of the cover can be colored in $N \leq d+1$ colors in such a way that for every two subsets U_i, U_j of the same color $\overline{U_i} \cap \overline{U_j} = \emptyset$. For $\alpha \in \{1, ..., N\}$ denote by I_α the set of all indices i such that U_i is of color α. Put $W_\alpha = \sqcup_{i \in I_\alpha} U_i$. The cover $\mathcal{U}$ is a refinement of $\{W_\alpha\}$. Since W_α is the disjoint union of Liouville domains, it is again a Liouville domain with

$$\chi(W_\alpha) = \max_{i \in I_\alpha} \chi(U_i) \ ,$$

so that $\chi(\mathcal{W}) = \chi(\mathcal{U})$. This completes the proof. □

4.6 Regularity of greedy covers

In this section we justify the claim of Example 4.5. Let $\mathcal{U}$ be a greedy cover responsible for the phase space discretization into Riemannian balls of radius r, see Example 3.1 above. We identify the vertices of the graph Υ with the set Z consisting of the centers of the balls. With this language $z, w \in Z$ are connected by an edge if and only if $\rho(z, w) \leq 2r$. For a vertex $z \in Z$ we denote by $St_k(z) \subset M$ its k-star. We tacitly assume that all the distances appearing below are small in comparison with the injectivity radius of the Riemannian metric ρ.

Step 1: Fix $k \in \mathbb{N}$. We claim that $D(z, kr) \subset St_k(z)$ for all sufficiently small r. Indeed, suppose that $\rho(z, w) \leq kr$, where $k \in \mathbb{N}$ and $z \in Z$. Joining z and w with the shortest geodesic and partitioning, we get points

$$u_0 = z, u_1, ..., u_{k-1}, u_k = w$$

with $\rho(u_i, u_{i+1}) \leq r$ for all $i = 0, ..., k-1$. Each points u_i lies at the distance $< r/2$ from some point $u'_i \in Z$, where we put $u'_0 = z$. By the triangle inequality, $\rho(u'_i, u'_{i+1}) < 2r$ and hence the graph distance $\gamma(z, u'_k)$ is $\leq k$. Since $w \in D(u'_k, r)$ we conclude that $w \in St_k(z)$. The claim follows.

Step 2: We claim that the degree of every vertex $z \in Z$ in the graph Υ is $\leq d$ where d depends only on the Riemannian metric. Indeed, let $v(r)$ (resp. $V(r)$) be the minimal (resp. the maximal) volume of the Riemannian ball of radius r on M. Put

$$b = \sup_{0<r<r_0} V(3r)/v(r/4) \ .$$

Let d_z be the degree of a vertex $z \in Z$ in the graph Υ and Y be the set of neighbors of z. Since the distance between each two of the neighbors is $> r/2$, the balls $D(y, r/4)$, $y \in Y$ are pairwise disjoint. At the same time $\rho(z, y) \leq 2r$ for all $y \in Y$ and hence $D(y, r/4) \subset D(z, 3r)$. Therefore,

$$\sqcup_{y \in Y} D(y, r/4) \subset D(z, 3r) \ .$$

It follows that $d_z \cdot v(r/4) \leq V(3r)$ and hence $d \leq b$.

Step 3: Choose $r_1 > 0$ small enough such that for every j and $0 < r < r_1$ the ball $D(z, r)$ lies in a Darboux chart of (M, ω). We can assume that for every $z \in Z$ this chart is identified with the standard symplectic ball $B(r_2) \subset \mathbb{R}^{2n}$, where z corresponds to the origin $0 \in \mathbb{R}^{2n}$. Furthermore, for some positive constants $a < b$

$$B(ar) \subset D(z, r) \subset B(br) \ \ \forall r \in (0, r_1), z \in Z \ .$$

In particular, we have that for r small enough

$$D(z, r) \subset B(br) \subset B(10br) \subset D(z, cr), \ \ c = 10b/a \ .$$

Fix an integer $p > c$. By Step 1 we have that $D(z, cr) \subset St_p(z)$. Comparing the displacement energies we get that

$$E(D(z, r), St_p(z)) \leq E(B(br), B(10br)) = \pi b^2 r^2 \ .$$

Therefore the greedy cover $\mathcal{U}$ is (d, p)-regular with $E_p(\mathcal{U}) \leq \pi b^2 r^2$. This proves the claim of Example 4.5. ☐

5 Symplectic geometry of fine covers

The rest of this section is dedicated to the proof of Theorem 4.8.

5.1 Algebraic preliminaries

Let us recall algebraic preliminaries which are borrowed from [16]. Let $\mathcal{G}$ be a group, and let $c : \mathcal{G} \to \mathbb{R}$ be a function with the following properties:

(i) $c(1) = 0$;

(ii) $c(\phi\psi\phi^{-1}) = c(\psi) \ \ \forall \phi, \psi \in \mathcal{G}$;

(iii) $c(\phi\psi) \leq c(\phi) + c(\psi)$.

We start with the following two observations. First, the function

$$q(\phi) := c(\phi) + c(\phi^{-1})$$

is a pseudo-norm on G. This means, by definition, that $q(1) = 0$, q is symmetric: $q(\phi) = q(\phi^{-1})$, and q satisfies the triangle inequality $q(\phi\psi) \leq q(\phi) + q(\psi)$. In addition, q is conjugation invariant: $q(\phi\psi\phi^{-1}) = q(\psi)$.

Second, we claim that for every $\phi \in \mathcal{G}$ the limit

$$\sigma(\phi) := \lim_{k\to\infty} c(\phi^k)/k$$

is well defined. Indeed, put $a_k = kc(\phi^{-1}) + c(\phi^k)$. Then $a_k \geq c(\phi^{-k}) + c(\phi^k) \geq 0$ and $a_{k+l} \leq a_k + a_l$. The subadditivity implies that the limit $\lim_{k\to\infty} a_k/k$ is well defined, and hence $\sigma(\phi)$ is well defined. The claim follows.

Proposition 5.1.

$$|\sigma(\phi\psi) - \sigma(\phi) - \sigma(\psi)| \leq \min(q(\phi), q(\psi)) \tag{29}$$

for all $\phi, \psi \in \mathcal{G}$.

Proof. We start with the formula

$$(\phi\psi)^k = \theta\phi^k, \quad \text{where} \quad \theta = \prod_{i=1}^{k} \phi^i\psi\phi^{-i} \, . \tag{30}$$

1) Note that

$$kc(\psi^{-1})+c(\psi^k)\geq c(\psi^{-k})+c(\psi^k)\geq 0\ ,$$

and hence

$$kc(\psi)=kq(\psi)-kc(\psi^{-1})\leq kq(\psi)+c(\psi^k)\ .$$

By (30)

$$c((\phi\psi)^k)\leq c(\theta)+c(\phi^k)\leq kc(\psi)+c(\phi^k)\leq kq(\psi)+c(\psi^k)+c(\phi^k)\ .$$

Dividing by k and passing to the limit as $k\to\infty$ we get that

$$\sigma(\phi\psi)-\sigma(\phi)-\sigma(\psi)\leq q(\psi)\ . \tag{31}$$

2) Note that

$$kc(\psi^{-1})=-kc(\psi)+kq(\psi)\leq -c(\psi^k)+kq(\psi)\ .$$

By (30),

$$c(\phi^k)\leq c(\theta^{-1})+c((\phi\psi)^k)\leq kc(\psi^{-1})+c((\phi\psi)^k)\ .$$

Combining these inequalities we get that

$$c(\phi^k)\leq -c(\psi^k)+kq(\psi)+c((\phi\psi)^k)\ .$$

Rearranging the terms, dividing by k and passing to the limit as $k\to\infty$ we get that

$$\sigma(\phi\psi)-\sigma(\phi)-\sigma(\psi)\geq -q(\psi)\ .$$

Together with (31) this yields

$$|\sigma(\phi\psi)-\sigma(\phi)-\sigma(\psi)|\leq q(\psi)\ .$$

Since c is conjugation invariant, σ is also conjugation invariant and thus $\sigma(\phi\psi)=\sigma(\psi\phi)$. Repeating the above arguments we get that

$$|\sigma(\phi\psi)-\sigma(\phi)-\sigma(\psi)|\leq q(\phi)\ .$$

Together with the previous inequality this yields (29). □

5.2 Spectral invariants

Let (M, ω) be a closed symplectic manifold. Denote by $\mathcal{F}$ the space of all smooth functions $F : M \times [0,1] \to \mathbb{R}$. Given such an F, we write $F_t(z) := F(z,t)$. For an open subset $U \subset M$ introduce the subspace $\mathcal{F}(U)$ consisting of all $F \in \mathcal{F}$ such that F_t is supported in U for all $t \in [0;1]$. Let $\mathcal{G}$ be the universal cover of the group of Hamiltonian diffeomorphisms of (M, ω). Given a Hamiltonian $F \in \mathcal{F}$, we write ϕ_F^t for the Hamiltonian flow generated by F, and ϕ_F for the element of $\mathcal{G}$ represented by the path $\{\phi_F^t\}$, $t \in [0;1]$. Given an open subset $U \in M$, Hamiltonians from $\mathcal{F}(U)$ generate a subgroup $\mathcal{G}(U) \subset \mathcal{G}$.

In what follows we are going to use the technique of spectral invariants introduced in [35, 29]. We denote by $c : \mathcal{G} \to \mathbb{R}$ the spectral invariant associated to the fundamental class of M. The function c satisfies properties (i)-(iii) from Section 5.1 above. We keep notations $q(\phi) = c(\phi) + c(\phi^{-1})$ and $\sigma(\phi) = \lim_{k\to\infty} c(\phi^k)/k$ introduced in this section. For a function $F \in \mathcal{F}$ define its mean value as

$$\langle F \rangle = \frac{\int_0^1 \int_M F\, \omega^n \cdot dt}{\int_M \omega^n} \,,$$

where $\dim M = 2n$. Introduce the *partial symplectic quasi-state* [16] $\zeta : C^\infty(M) \to \mathbb{R}$ by

$$\zeta(F) = \sigma(\phi_F) + \langle F \rangle \,.$$

Let us list some additional properties of these functionals which will be used below (see [16, 17]):

STABILITY:

$$|(c(\phi_F) + \langle F \rangle) - (c(\phi_G) + \langle G \rangle)| \leq \int_0^1 ||F_t - G_t||\, dt \tag{32}$$

and

$$|(\sigma(F) + \langle F \rangle) - (\sigma(\phi_G) + \langle G \rangle)| \leq \int_0^1 ||F_t - G_t||\, dt \,. \tag{33}$$

HOMOGENEITY: The functional ζ is $\mathbb{R}_+$-homogeneous: $\zeta(sF) = s\zeta(F)$ for all $s > 0$.

VANISHING: A key property of ζ is that $\zeta(F) = 0$ provided the support of F is displaceable. Further (see [16])

$$q(\phi) \leq 2E(U) \;\; \forall \phi \in \mathcal{G}(U) \,, \tag{34}$$

where $E(U)$ is the displacement energy of U.

SPECTRALITY (SEE [36]): Finally, let us mention that the number $c(\phi)$ necessarily lies in *the action spectrum of* ϕ, a special subset associated to a (lift of a) Hamiltonian diffeomorphism $\phi \in \mathcal{G}$ as follows: Represent ϕ as ϕ_F for some Hamiltonian $F \in \mathcal{F}$. Let $\gamma = \{\phi_F^t x\}$, $t \in [0,1]$ be a contractible closed orbit of the Hamiltonian flow of F, that is $\phi_F^1 x = x$. Choose any two-dimensional disc $D \subset M$ spanning γ. By definition,

$$\text{Action}(\gamma, D) = \int_0^1 F(\phi_F^t x, t)\, dt - \int_D \omega \ .$$

The action spectrum $\text{spec}(\phi) \subset \mathbb{R}$ is defined as the set of actions of all closed orbits of ϕ with respect to all spanning discs D. The action spectrum does not depend on the specific Hamiltonian F generating ϕ and is nowhere dense in $\mathbb{R}$. Moreover, if $\pi_2(M) = 0$, all discs D spanning a given orbit γ are homotopic with fixed boundary, so that $\int_D \omega$ does not depend on D. In this case $\text{spec}(\phi)$ is a compact subset of $\mathbb{R}$.

5.3 The Poisson bracket inequality

For $F, G \in C^\infty(M)$ put

$$\Pi(F,G) = |\zeta(F+G) - \zeta(F) - \zeta(G)| \ \text{ and } \ S(F,G) = \sup_{s>0} \min(q(\phi_{sF}), q(\phi_{sG})) \ .$$

Observe that by (34)

$$S(F,G) \le 2\min(E(\text{supp}F), E(\text{supp}G)) \ . \tag{35}$$

The next proposition is a modification of a result from [17].

Proposition 5.2. *For every functions* $F, G \in C^\infty(M)$

$$\Pi(F,G) \le \sqrt{2S(F,G) \cdot ||\{F,G\}||}. \tag{36}$$

Proof. Let f_t, g_t be the Hamiltonian flows of F, G, respectively. Set $H = F + G$, $K_t = F + G \circ f_t^{-1}$. Observe that $\phi_K = \phi_F \, \phi_G$. Calculating

$$G(f_t x) - G(x) = \int_0^t \frac{d}{ds} G(f_s x) ds = \int_0^t \{G, F\}(f_s x) ds \ ,$$

we get that $||H - K_t|| = ||G - G \circ f_t^{-1}|| = ||G \circ f_t - G|| \leq t||\{F, G\}||$. Since $\langle K \rangle = \langle F + G \rangle$, we have by (33) that

$$|\sigma(\phi_{F+G}) - \sigma(\phi_F\, \phi_G)| \leq \int_0^1 ||H - K_t||\; dt \leq \frac{1}{2}||\{F, G\}||.$$

Then

$$\Pi(F, G) = |\sigma(\phi_{F+G}) - \sigma(\phi_F) - \sigma(\phi_G)| \leq |\sigma(\phi_{F+G}) - \sigma(\phi_F\, \phi_G)| \\ + |\sigma(\phi_F\, \phi_G) - \sigma(\phi_F) - \sigma(\phi_G)| \leq \frac{1}{2}||\{F, G\}|| + I\ , \quad (37)$$

where $I := |\sigma(\phi_F\, \phi_G) - \sigma(\phi_F) - \sigma(\phi_G)|$. By Proposition 5.1, $I \leq S(F, G)$, and therefore

$$\Pi(F, G) \leq \frac{1}{2}||\{F, G\}|| + S(F, G)\ . \quad (38)$$

Let us balance this inequality: Take any $s > 0$, and note that

$$\Pi(sF, sG) = s \cdot \Pi(F, G),\ \ ||\{sF, sG\}|| = s^2||\{F, G\}||,\ \ S(sF, sG) = S(F, G)\ .$$

Substituting into (38) and dividing by s we obtain

$$\Pi(F, G) \leq \frac{1}{2}s||\{F, G\}|| + \frac{S(F, G)}{s}.$$

The right hand side is minimized by $s = \sqrt{2S(F, G)/||\{F, G\}||}$, which yields

$$\Pi(F, G) \leq \sqrt{2S(F, G) \cdot ||\{F, G\}||}.$$

□

Corollary 5.3. *Let* $\mathcal{W} = \{W_1, ..., W_N\}$ *be an open cover of* M *by displaceable open subsets. Assume that for every* j

$$\sup_{\phi \in \mathcal{G}(W_j)} q(\phi) \leq Q\ . \quad (39)$$

Then

$$pb(\mathcal{W}) \geq 1/(2N^2 Q)\ . \quad (40)$$

Proof. Let $\vec{f} = \{f_1, ..., f_N\}$ be any partition of unity subordinated to $\mathcal{W}$. Observe that $\zeta(f_i) = 0$ since the support of f_i is displaceable. Put $g_k = f_1 + ... + f_k$. By (36),

$$\zeta(g_{k+1}) \leq \zeta(g_k) + \sqrt{2Q\nu_c(\vec{f})} \ .$$

Thus

$$1 = \zeta(g_N) \leq N\sqrt{2Q\nu_c(\vec{f})} \ ,$$

and hence $\nu_c(\vec{f}) \geq 1/(2N^2Q)$. This yields (40). □

5.4 Proof of main theorems on fine regular covers

Proof of Theorem 4.8(i): Let (M, ω) be a closed symplectic manifold, and let $\mathcal{W} = \{W_1, ..., W_N\}$ be an open cover of M such that all subsets W_j are displaceable with $E(W_j) \leq \mathcal{A}$. Applying Corollary 5.3 combined with formula (34) to the cover $\mathcal{W}$ we get that

$$pb(\mathcal{W}) \geq C(N) \cdot \mathcal{A}^{-1} \ ,$$

the positive constant $C(N)$ depends only on N. □

In order to prove the second part of the main theorem, we shall need the following auxiliary statement.

Proposition 5.4. *Let (M, ω) be a closed symplectic manifold with $\pi_2(M) = 0$. Let $\overline{W} \subset M$ be a portable closed Liouville domain. Then for every $\phi \in \mathcal{G}(W)$*

$$q(\phi) \leq 2\chi(W) \tag{41}$$

Recall that according to our conventions, W is the interior of $\overline{W}$ and all connected components of $\overline{W}$ (and hence of W) are simply connected.

Proof. Let R_τ, $\tau < 0$ be the flow of the Liouville vector field. Take any $u \in (0, 1)$ such that uW is displaceable in W with the displacement energy E_u. Suppose that $\phi = \phi_F$, where $F \in \mathcal{F}(W)$. Write f_t for the Hamiltonian flow of F so that $f_1 = \phi$. Define a path of Hamiltonian diffeomorphisms $f_t^{(s)}$,

$s \in [u,1]$ as $R_{\log s} f_t R^{-1}_{\log s}$ on sW and as the identity outside sW. Observe that for every s the path $\{f^{(s)}_t\}$ is generated by the Hamiltonian

$$F_s(z,t) = sF(R^{-1}_{\log s} z, t) \ . \tag{42}$$

Put $\phi^{(s)} = f^{(s)}_1$.

Consider the following subset of the plane $\mathbb{R}^2$ equipped with the coordinates (s,a): for every $s \in [u,1]$ mark on the line $s \times \mathbb{R}$ the action spectrum of $\phi^{(s)}$. We claim that this set is a disjoint union of segments lying on straight lines passing through the origin. Indeed, γ is a contractible closed orbit of $\{f_t\}$ if and only if $\gamma_s := R_{\log s}\gamma$ is a contractible closed orbit of $\{f^{(s)}_t\}$. Since $\pi_2(M) = 0$, the action of a contractible closed orbit does not depend on the choice of the spanning disc. Since W is simply connected, γ can be spanned by a disc $D \subset W$, and hence γ_s can be spanned by $D_s := R_{\log s} D$. Taking into account that $\int_{D_s} \omega = s \cdot \int_\omega D$ and by using (42) we get that

$$\text{Action}(\gamma_s, D_s) = s \cdot \text{Action}(\gamma, D) \ .$$

This yields the claim. Remembering that the action spectrum is nowhere dense and that $c(\phi^{(s)}) \in \text{spec}(\phi^{(s)})$ depends continuously on s, we conclude that $c(\phi^{(s)}) = sc(\phi)$. Similarly, $c((\phi^{(s)})^{-1}) = sc(\phi^{-1})$, and so $q(\phi^{(s)}) = sq(\phi)$ for all $s \in [u,1]$. By (34), $q(\phi^{(u)}) \leq 2E_u$ and hence $q(\phi) \leq 2E_u/u$. Passing to the limit as $u \to 0$, we get that $q(\phi) \leq 2\chi(W)$, as required. $\square$

Proof of Theorem 4.8(ii) Let (M,ω) be a closed symplectic manifold with $\pi_2(M) = 0$. Consider a cover $\mathcal{W} = \{W_1, ..., W_N\}$ such that all subsets subsets W_j are Liouville with $\chi(W_j) \leq \mathcal{A}$. By Proposition 5.4

$$\sup_{\phi \in \mathcal{G}(W_j)} q(\phi) \leq 2\mathcal{A} \tag{43}$$

for every $j = 1, ..., N$. Applying Corollary 5.3 to the cover $\mathcal{W}$ we get that $pb(\mathcal{W}) \geq C(N)\mathcal{A}^{-1}$. $\square$

6 Geometry of overlaps

6.1 pb_4-invariant

We start with the definition of the Poisson bracket invariant pb_4, which was introduced and studied in [5]. Let X_0, X_1, Y_0, Y_1 be a quadruple of compact subsets of a symplectic manifold (M, ω) satisfying an intersection condition

$$X_0 \cap X_1 = Y_0 \cap Y_1 = \emptyset \;.$$

One of the equivalent definitions of pb_4 is as follows, see [5, Proposition 1.3]:

$$pb_4(X_0, X_1, Y_0, Y_1) = \inf ||\{f, g\}|| \;,$$

where the infimum is taken over all pairs of functions $f, g : M \to [0; 1]$ with $f = 0$ near X_0, $f = 1$ near X_1, $g = 0$ near Y_0 and $g = 1$ near Y_1.

Example 6.1. Consider the unit sphere S^2 equipped with the standard area form. Let $\Pi \subset S^2$ be a quadrilateral whose edges (in the cyclic order) are denoted by u_1, v_1, u_2, v_2. By [5, Theorem 1.20]

$$pb_4(u_1, u_2, v_1, v_2) = \max \Big(1/\text{Area}(\Pi), 1/(\text{Area}(S^2) - \text{Area}(\Pi)\Big) \;. \tag{44}$$

The proof of (44) presented in [5] is elementary. Let us mention, however, that proving positivity of pb_4 in specific examples on symplectic manifolds of dimension ≥ 4 involves "hard" symplectic techniques such as theory of symplectic quasi-states (cf. Section 5.2 above) and/or the Donaldson-Fukaya category (see [5]). Interestingly enough, both tools have strong links to physics: the former is related to a discussion on non-contextual hidden variables in quantum mechanics, while the latter comes from mirror symmetry.

In what follows we shall need the following obvious monotonicity property of pb_4 (see [5, Section 2]: Assume that subsets X_0', X_1', Y_0', Y_1' are contained in X_0, X_1, Y_0, Y_1 respectively. Then

$$pb_4(X_0', X_1', Y_0', Y_1') \leq pb_4(X_0, X_1, Y_0, Y_1) \;. \tag{45}$$

Furthermore, $pb_4(X_0, X_1, Y_0, Y_1)$ is invariant under permutations X_0 with X_1, Y_0 with Y_1 and of the pairs (X_0, X_1) and (Y_0, Y_1).

For a subset $U \subset M$ denote by $U^c := M \setminus U$ its set-theoretic complement. Let $\mathcal{U} = \{U_1, ..., U_L\}$ be an open cover of a topological space M. Given a subset $I \subset \Omega_L = \{1, ..., L\}$, put

$$U(I) := \Big(\bigcup_{\alpha \in I} U_\alpha\Big)^c \;, \tag{46}$$

and

$$\Lambda(\mathcal{U}, I) = \bigcup_{\alpha \in I, \beta \in I^c} U_\alpha \cap U_\beta \ . \tag{47}$$

The subset $U(I)$ is closed and $\Lambda(\mathcal{U}, I)$ is open. The manifold M is decomposed into the union of three disjoint subsets

$$M = U(I) \sqcup \Lambda(\mathcal{U}, I) \sqcup U(I^c) \ . \tag{48}$$

We call $\Lambda(\mathcal{U}, I)$ *an overlap layer* of the cover U.

The main result of the present section is as follows.

Theorem 6.2. *Let $\mathcal{U} = \{U_1, ..., U_L\}$ and $\mathcal{V} = \{V_1, ..., V_N\}$ be two finite open covers of M. Then for every $I \subset \Omega_L$ and $J \subset \Omega_N$*

$$pb(\mathcal{U}, \mathcal{V}) \geq 4pb_4(U(I), U(I^c), V(J), V(J^c)) \ . \tag{49}$$

In view of decomposition (48), the value of $pb_4(U(I), U(I^c), V(J), V(J^c))$ depends only on relative position of overlap layers $\Lambda(\mathcal{U}, I)$ and $\Lambda(\mathcal{V}, J)$. Note also, that since $pb(\mathcal{U}, \mathcal{U}) = pb(\mathcal{U})$ by (20), the theorem is applicable to a single cover. It implies that for all I, J

$$pb(\mathcal{U}) \geq 4pb_4(U(I), U(I^c), U(J), U(J^c)) \ . \tag{50}$$

6.2 Two-sets covers

Consider a pair of open covers consisting of exactly two sets, $\mathcal{U} = \{U_1, U_2\}$ and $\mathcal{V} = \{V_1, V_2\}$. The corresponding partitions of unity necessarily have the form $f, 1 - f$ and $g, 1 - g$. It turns out that in this case the Poisson bracket invariant pb coincides (up to a multiple) with the invariant pb_4 introduced in Section 6.1 above. Recall that U^c stands for the complement $M \setminus U$ of a subset $U \subset M$.

Proposition 6.3. *Let $\mathcal{U} = \{U_1, U_2\}$ and $\mathcal{V} = \{V_1, V_2\}$ be two open covers of a closed symplectic manifold (M, ω). Then*

$$pb(\mathcal{U}, \mathcal{V}) = 4pb_4(U_1^c, U_2^c, V_1^c, V_2^c) \ . \tag{51}$$

Proof. 1) Consider two partitions of unity $f, 1-f$ and $g, 1-g$ denoted by S_f and S_g respectively. Observe that they are Poisson commutative and hence $\nu_c(S_f) = \nu_c(S_g) = 0$. We claim that

$$\nu_c(S_f, S_g) = 4||\{f, g\}|| \; . \tag{52}$$

Indeed,

$$\{x_1 f + x_2(1-f), y_1 g + y_2(1-g)\} = (x_1 - x_2)(y_1 - y_2)\{f, g\} \; .$$

Maximizing over $x_i, y_j \in [-1, 1]$, we get (52).

2)Let $\mathcal{U} = \{U_1, U_2\}$ and $\mathcal{V} = \{V_1, V_2\}$ be two open covers of M. Consider any two partitions of unity $f, 1-f$ and $g, 1-g$ subordinated to $\mathcal{U}$ and $\mathcal{V}$ respectively. Denote them by S_f and S_g. Since $\operatorname{supp}(f) \subset U_1$,

$$U_1^c \subset W := M \setminus \operatorname{supp}(f) \; .$$

Note that f vanishes on W and hence f vanishes near U_1^c. Similarly, $f = 1$ near U_2^c, $g = 0$ near V_1^c and $g = 1$ near V_2^c. Therefore by (52)

$$pb(\mathcal{U}, \mathcal{V}) \geq 4p \; , \tag{53}$$

where $p := pb_4(U_1^c, U_2^c, V_1^c, V_2^c)$.

3) Consider any pair of functions $f, g : M \to [0; 1]$ so that $f = 0$ near U_1^c, $f = 1$ near U_2^c, $g = 0$ near V_1^c and $g = 1$ near V_2^c. In particular, f vanishes on some open set X containing U_1^c. Therefore the open subset $\{f \neq 0\}$ is contained in a closed subset X^c. Thus

$$\operatorname{supp}(f) \subset X^c \subset U_1 \; .$$

Applying the same argument to the functions $1-f$,g and $1-g$ we get that $f, 1-f$ and $g, 1-g$ are partitions of unity subordinated to covers $\mathcal{U}$ and $\mathcal{V}$ respectively. By (52), we have that $4p \geq pb(\mathcal{U}, \mathcal{V})$. Together with (53) this yields $pb(\mathcal{U}, \mathcal{V}) = 4p$, as required. □

6.3 Proof of Theorem 6.2

Let $\mathcal{U} = \{U_1, ..., U_L\}$ and $\mathcal{V} = \{V_1, ..., V_N\}$ be open covers of M. Fix non-empty subsets $I \subset \Omega_L = \{1, ..., L\}$ and $J \subset \Omega_N$. We shall assume that their complements I^c and J^c are non-empty. Put

$$W_1 = \bigcup_{\alpha \in I} U_\alpha, \;\; W_2 = \bigcup_{\beta \in I^c} U_\beta \; ,$$

$$Z_1 = \bigcup_{\alpha \in J} V_\alpha, \;\; Z_2 = \bigcup_{\beta \in J^c} V_\beta \;.$$

With this notation (cf. formula (46))

$$U(I) = W_1^c, \; U(I^c) = W_2^c, \; V(J) = Z_1^c, V(J^c) = Z_2^c \;.$$

Take arbitrary partitions of unity $\vec{f} = \{f_1, ..., f_L\}$ and $\vec{g} = \{g_1, ..., g_N\}$ subordinated to $\mathcal{U}$ and $\mathcal{V}$ respectively. Put $\phi := \sum_{\alpha \in I} f_\alpha$ and $\psi := \sum_{\alpha \in J} g_\alpha$. Then $1 - \phi = \sum_{\beta \in I^c} f_\beta$ and $1 - \psi = \sum_{\beta \in J^c} g_\beta$. Thus for $x_1, x_2 \in [-1; 1]$

$$x_1 \phi + x_2 (1 - \phi) = x_1 \sum_{\alpha \in I} f_\alpha + x_2 \sum_{\beta \in I^c} f_\beta \;, \tag{54}$$

and

$$x_1 \psi + x_2 (1 - \psi) = x_1 \sum_{\alpha \in J} g_\alpha + x_2 \sum_{\beta \in J^c} g_\beta \;. \tag{55}$$

Observe that the partition of unity S_ϕ consisting of $\phi, 1 - \phi$ is subordinated to the cover $\mathcal{W} := \{W_1, W_2\}$, and the partition of unity S_ψ consisting of $\psi, 1 - \psi$ is subordinated to the cover $\mathcal{Z} := \{Z_1, Z_2\}$. By (54) and (55)

$$\nu_c(\vec{f}, \vec{g}) \geq \nu_c(S_\phi, S_\psi) \;.$$

Since S_ϕ and S_ψ are commutative partitions of unity, this yields

$$pb(\mathcal{U}, \mathcal{V}) \geq pb(\mathcal{W}, \mathcal{Z}) = 4 pb_4(U(I), U(I^c), V(J), V(J^c)) \;,$$

where last equality follows from Proposition 6.3 above. □

7 Back to quantum mechanics

7.1 Phase space discretization: a noise-localization uncertainty relation

Let (M, ω) be a quantizable closed symplectic manifold. Let $\mathcal{U}$ be either a (d, p)-regular cover, or a degree $\leq d$ Liouville cover. In the latter case assume that $\pi_2(M) = 0$. Write $\mathcal{A}$ for the magnitude of localization of $\mathcal{U}$. Combining Theorem 3.6(i) with (28) we get the following lower bound on the noise indicator of $\mathcal{U}$:

$$\mu(\mathcal{U}) \geq C \mathcal{A}^{-1} \;, \tag{56}$$

where the constant C depends only on d and p (in the case of Liouville covers, only on d).

This inequality can be spelled out as follows. Fix a scheme of the Berezin-Toeplitz quantization $T_m : C^\infty(M) \to \mathcal{L}(H_m)$. For any partition of unity $\vec{f} = \{f_i\}$ of M subordinated to $\mathcal{U}$ consider the POVM $A^{(m)} = \{T_m(f_j)\}$ corresponding to the quantum registration problem associated to $\mathcal{U}$. Recalling the definition of the noise indicator and the equality $\hbar = 1/m$ we get the following *noise-localization uncertainty relation* stated in Theorem 1.1:

$$\mathcal{N}_{in}(A^{(m)}) \cdot \mathcal{A} \geq C\hbar \quad \forall m \geq m_0 \;, \tag{57}$$

where the number m_0 depends on the Berezin-Toeplitz quantization T and the partition of unity $\{f_j\}$. In other words, a sufficiently fine phase-space localization of the system yields inherent quantum noise.

7.2 Overlap induced noise

Let $\mathcal{U} = \{U_1, ..., U_L\}$ and $\mathcal{V} = \{V_1, ..., V_N\}$ be two finite open covers of a closed quantizable symplectic manifold (M, ω). Consider POVMs $A^{(m)} = \{T_m(f_i)\}$ and $B^{(m)} = \{T_m(g_j)\}$, where $\vec{f} = \{f_i\}$ and $\vec{g} = \{g_j\}$ are partitions of unity on M, associated to a pair of registration procedures. Let $C^{(m)}$ be any joint observable of $A^{(m)}$ and $B^{(m)}$ existing by Proposition 3.4. Combining Theorems 3.6(ii) and Theorem 6.2 we get that for all $I \subset \Omega_L$ and $J \subset \Omega_N$

$$\mathcal{N}_{in}(C^{(m)}) \geq 2pb_4(U(I), U(I^c), V(J), V(J^c)) \cdot \hbar$$

for all sufficiently large quantum numbers m. A similar statement holds true in the case of a single cover, see Theorem 1.2 of the introduction which is an immediate consequence of Theorem 3.6(i), equality (20) and Theorem 6.2.

Interestingly enough, in certain situations geometry of overlaps provides better bounds for the inherent noise than the ones coming from the phase space localization. Let us illustrate this in the context of joint measurements of POVMs associated to a pair of registration procedures. Let (M, ω) be a quantizable closed symplectic manifold. Consider a pair of open covers consisting of exactly two sets, $\mathcal{U} = \{U_1, U_2\}$ and $\mathcal{V} = \{V_1, V_2\}$. The corresponding partitions of unity necessarily have the form $f, 1-f$ and $g, 1-g$. The Berezin-Toeplitz quantization takes these partitions into commutative POVMs $T_m(f), \mathbb{1} - T_m(f)$ and $T_m(g), \mathbb{1} - T_m(g)$ on the two-point space Ω_2. Each of them is a *simple* observable in the terminology of [11]. We refer to

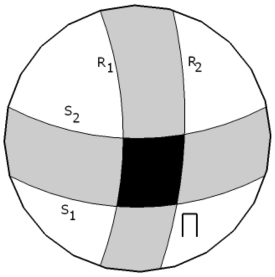

Figure 3: A pair of covers of the sphere by two discs.

[11] for various results on joint measurements of a pair of simple observables. Applying inequality (49) with $I = J = \{1\} \subset \Omega_2$, we get that for the two-set covers

$$\mu(\mathcal{U}, \mathcal{V}) \geq 2pb_4(U_1^c, U_2^c, V_1^c, V_2^c) \ . \tag{58}$$

Example 7.1. Consider the unit sphere S^2 equipped with the standard area form. Consider a pair of two-set covers $\mathcal{U}$ and $\mathcal{V}$ such that U_1, U_2, V_1, V_2 are topological discs with smooth boundaries and the overlap layers $\Lambda(U) := U_1 \cap U_2$ and $\Lambda(V) := V_1 \cap V_2$ are annuli with the boundaries

$$\partial\Lambda(U) = \partial U_1 \sqcup \partial U_2, \ \ \partial\Lambda(V) = \partial V_1 \sqcup \partial V_2 \ .$$

Assume that the intersection $\Lambda(U) \cap \Lambda(V)$ contains a quadrilateral Π with edges (in cyclic order) u_1, v_1, u_2, v_2 lie on $R_1 := \partial U_1, S_1 := \partial V_1, R_2 := \partial U_2, S_2 := \partial V_2$ respectively. This is illustrated on Fig. 3, where the disc U_1 lies to the right of the circle R_1, U_2 to the left of R_2, V_1 above S_1 and V_2 below S_2. The overlap layers $U_1 \cap U_2$ and $V_1 \cap V_2$ are gray while the quadrilateral Π is black. Observe that by (45) and (44)

$$pb_4(U_1^c, U_2^c, V_1^c, V_2^c) \geq pb_4(u_1, u_2, v_1, v_2) \geq \frac{1}{\text{Area}(\Pi)} \ ,$$

and hence by (58)

$$\mu(\mathcal{U},\mathcal{V}) \geq \frac{2}{\text{Area}(\Pi)} \; . \tag{59}$$

Another route which could lead to the lower bound on the noise indicator $\mu(\mathcal{U},\mathcal{V})$ is as follows: Recall that by Proposition 4.2 $pb(\mathcal{U},\mathcal{V}) \geq pb(\mathcal{U}\cdot\mathcal{V})/4$, and hence

$$\mu(\mathcal{U},\mathcal{V}) \geq \frac{1}{8}\cdot pb(\mathcal{U}\cdot\mathcal{V}) \; . \tag{60}$$

For instance, in the situation sketched on Figure 3 the cover $\mathcal{U}\cdot\mathcal{V}$ consists of four discs. Denote by $\mathcal{A}$ the maximal area of these discs which can be interpreted as the magnitude of localization. Since each of these discs (after an appropriate smoothing of the boundaries) is a portable Liouville domain, Theorem 4.8(ii) together with (60) would yield

$$\mu(\mathcal{U},\mathcal{V}) \geq C\cdot\mathcal{A}^{-1} \; ,$$

where C is a numerical constant. This bound on the noise indicator is worse than (59) when $\text{Area}(\Pi) \ll \mathcal{A}$, or, in other words, when the "characteristic scale" appearing in the relative geometry of the overlap layers $U_1\cap U_2$ and $V_1\cap V_2$ is much smaller then the magnitude of localization.

7.3 Quantum registration and approximate measurements

We start this section with some preliminaries on approximate measurements. Denote by $\mathcal{S}$ the set of (not necessarily pure) quantum states $\rho \in \mathcal{L}(H)$, $\rho \geq 0$, $\text{trace}(\rho)=1$. As usually, a pure state $[\xi]\in\mathbb{P}(H)$ is identified with the projector $P\in\mathcal{S}$ to the line $[\xi]$. For a POVM B on $\mathbb{R}$ and a state $\rho\in\mathcal{S}$ we denote by ρ_B the corresponding probability measure on $\mathbb{R}$:

$$\rho_B(X) = \text{trace}(\rho\cdot B(X)) \; ,$$

for every Borel subset $X\subset\mathbb{R}$.

Let A be a POVM on $\mathbb{R}$ and E be a projector valued measure on $\mathbb{R}$. Roughly speaking, A is an approximation to E if for every state $\rho\in\mathcal{S}$ the probability distribution ρ_A is "close" to the probability distribution ρ_E. The importance of this notion is due to the fact that in various interesting situations, pairs of projector valued measures become jointly measurable only after a suitable approximation (see [12, 10]).

There exist several mathematical ways to formalize the notion of an approximate measurement. In what follows we stick to the one proposed in [12] which is based on *error bar widths*. Here is the precise definition (which is slightly simplified in comparison to [12] since we are dealing with POVMs on $\mathbb{R}$ supported in a finite set of points, cf. [26]): Fix $\epsilon \in (0;1)$. Given $x \in \mathbb{R}$ and $\delta > 0$ we write $J_{x,\delta}$ for the segment $[x-\delta/2, x+\delta/2]$. Denote by θ the infimum of the set of all $w > 0$ with the following property: for every $x \in \mathbb{R}$ and $\rho \in \mathcal{S}$

$$\rho_E(x) = 1 \Rightarrow \rho_A(J_{x,w}) \geq 1 - \epsilon \; .$$

We shall say that A *is an* ϵ*-approximation to* E *with the error bar width* θ.

Let us revisit Example 3.2 above: Take a smooth function $F : M \to \mathbb{R}$. Consider the closed interval $I := [\min F, \max F]$. Let $W_1, ..., W_N$ be a cover of I by N open intervals. The sets $U_k := \{F^{-1}(W_k)\}$ form an open cover $\mathcal{U}$ of M. Let $\vec{f} = \{f_1, ..., f_N\}$ be any partition of unity subordinated to $\mathcal{U}$. Applying the Berezin-Toeplitz quantization, we get a sequence of $\mathcal{L}(H_m)$-valued POVMs $A^{(m)} = \{A_k^{(m)}\}_{k=1,...,N}$ on Ω_N, where $A_k^{(m)} = T_m(f_k \circ F)$.

Assume that the system is prepared in a pure state $[\xi] \in \mathbb{P}(H_m)$, $|\xi| = 1$. The quantity

$$p_k := \langle T_m(h_k \circ F)\xi, \xi \rangle$$

can be interpreted as the probability of the event that the system is registered in the set $F^{-1}(W_k)$ (see [32, Section 8]), or, in other words, that the value of the observable F lies in the interval W_k.

In fact, we shall show now that *POVM* $A^{(m)}$ *provides an approximate measurement of the quantum observable* $E^{(m)} := T_m(F)$ *corresponding to* F. To make this statement precise, we transform $E^{(m)}$ and $A^{(m)}$ into POVMs on $\mathbb{R}$ as follows. In the case of $E^{(m)}$ we use the standard procedure from [8]: Let $E^{(m)} = \sum \lambda_j P_j$ be the spectral decomposition of $E^{(m)}$. Put $\widehat{E}^{(m)} := \sum P_j \delta_{\lambda_j}$ and consider it as an $\mathcal{L}(H_m)$-valued POVM on $\mathbb{R}$ representing the von Neumann observable $E^{(m)}$. In case of $A^{(m)}$ we choose in an arbitrary way points $x_k \in W_k$ and put $\widehat{A}^{(m)} = \sum A_k^{(m)} \delta_{x_k}$.

Theorem 7.2. *Suppose that the length of each interval* W_k, $k = 1, ..., N$ *is less than* c. *Then there exists a sequence of positive numbers* $\epsilon_m \to 0$ *as* $m \to \infty$ *so that the POVM* $\widehat{A}^{(m)}$ *is an* ϵ_m*-approximation to the sharp observable* $\widehat{E}^{(m)}$ *with the error bar width* θ *which satisfies*

$$\frac{\max F - \min F}{8N} \leq \theta \leq 2c \tag{61}$$

for all sufficiently large m.

Remark 7.3. Let F, G be a pair of smooth functions on M. Look at the corresponding operators $T_m(F)$ and $T_m(G)$ considered as (von Neumann) quantum observables. In general, these two observables are not jointly measurable. Theorem 7.2 combined with Proposition 3.4 above show that *they become jointly measurable after a suitable approximation.* The precision of the approximation tends to zero in the classical limit, while the error bar width remains bounded.

Proof of Theorem 7.2. Step 1: First of all we claim that for every continuous function h on $\mathbb{R}$

$$||T_m(h \circ F) - h(T_m(F))||_{op} \to 0 \ , \quad \text{as} \quad m \to \infty \ . \tag{62}$$

Indeed, (62) holds for polynomials by property (BT5) of the Berezin-Toeplitz quantization. Approximating h on $[-||F|| - 1, ||F|| + 1]$ in the uniform norm by a polynomial and applying (BT3), we get (62).

Step 2: Note that $J_{x,c} \cap W_j = \emptyset$ provided $x_j \notin J_{x,4c}$. For such a j the function f_j vanishes on the set $F^{-1}(J_{x,c})$ since it is supported in $F^{-1}(W_j)$. Therefore

$$\sum_{j : x_j \in J_{x,4c}} f_j(y) = 1 \quad \forall y \in F^{-1}(J_{x,c}) \ . \tag{63}$$

Step 3: Define a non-negative smooth cut off function $\psi : \mathbb{R} \to [0,1]$ so that $\psi(s) = 1$ when $|s| \leq c/8$ and $\psi(s) = 0$ when $|s| \geq c/4$. For $x \in \mathbb{R}$ put $\psi_x(s) = \psi(x - s)$. We claim that

$$\sum_{j : x_j \in J_{x,4c}} f_j \geq \psi_x \circ F \ . \tag{64}$$

Indeed, on $F^{-1}(J_{x,c})$ the inequality holds by (63), and outside $F^{-1}(J_{x,c})$ the inequality holds since $\psi_x \circ F$ vanishes on this set.

Step 4: For an interval $J \subset \mathbb{R}$ denote by I_J its indicator function. Observe that

$$\widehat{A}^{(m)}(J_{x,4c}) = \sum_{j : x_j \in J_{x,4c}} T_m(f_j) = T_m\Big(\sum_{j : x_j \in J_{x,4c}} f_j \Big) \ .$$

By (64),

$$T_m\Big(\sum_{j:x_j\in J_{x,4c}} f_j\Big) \geq T_m(\psi_x \circ F)\ .$$

By (62)

$$T_m(\psi_x\circ F) = \psi_x(T_m(F)) + o(1) \geq I_{J_{x,c/8}}(T_m(F)) + o(1)\ .$$

It follows that there exists a sequence of positive numbers $\epsilon_m \to 0$ so that

$$\widehat{A}^{(m)}(J_{x,4c}) \geq I_{J_{x,c/8}}(T_m(F)) - \epsilon_m \cdot 1\!\!1\ . \tag{65}$$

STEP 5: Recall that we denoted $E^{(m)} = T_m(F)$ and $\widehat{E}^{(m)} := \sum P_j\delta_{\lambda_j}$, where $E^{(m)} = \sum \lambda_j P_j$ is the spectral decomposition of $E^{(m)}$. Assume that $\rho_{\widehat{E}^{(m)}}(x) = 1$ for some state $\rho \in S$ and a point $x \in \mathbb{R}$. This means that

$$\mathrm{trace}(\rho\cdot \sum_{j:\lambda_j = x} P_j) = 1\ .$$

Since $\mathrm{trace}(\rho\cdot P_i) \geq 0$ for all i and

$$\mathrm{trace}(\rho\cdot\sum_i P_i) = \mathrm{trace}(\rho) = 1\ ,$$

it follows that

$$\mathrm{trace}(\rho\cdot I_{J_{x,c/8}}(T_m(F)) = 1\ .$$

By (65) we see that

$$\mathrm{trace}(\rho\cdot \widehat{A}^{(m)}(J_{x,4c})) \geq 1-\epsilon_m\ .$$

By definition, this means that $\widehat{A}^{(m)}$ is an ϵ_m-approximation of $\widehat{E}^{(m)}$ with the error bar width

$$\theta \leq 2c\ . \tag{66}$$

STEP 6: Let $J \subset (\min F, \max F)$ be a closed interval. We claim that $T_m(F)$ has an eigenvalue in J for all sufficiently large m. Indeed, let $J = J_{x,w}$. Define a non-negative cut off function $\phi : \mathbb{R} \to [0,1]$ so that $\phi(s) = 1$ when $|s-x| \leq w/8$ and $\phi(s) = 0$ when $|s| \geq w/4$. Assume on the contrary that $T_m(F)$ has no eigenvalues in J. Then $\phi(T_m(F)) = 0$. By Step 1,

$\phi(T_m(F)) = T_m(\phi(F)) + o(1)$. By property (BT3) of the Berezin-Toeplitz quantization, $||T_m(\phi(F))||_{op} = 1 + o(1)$. This contradiction proves the claim.

STEP 7: Put $\tau = \max F - \min F$. There exists an open interval $J_{y,w} \subset (\min F, \max F)$ with $0 < w \leq \tau/4N$ which does not contain any of the points x_j, $j = 1, ..., N$. By Step 6, $\widehat{E}^{(m)} = T_m(F)$ has an eigenvalue, say, x in $J_{y,w/2}$ for all sufficiently large m. Let $\rho \subset \mathcal{S}$ be the projector to one of the corresponding eigenvectors. Then $\rho_{\widehat{E}^{(m)}}(x) = 1$, while $\rho_{\widehat{A}^{(m)}}(J_{x,w/2}) = 0$. Thus the error bar width θ is $\geq \tau/8N$. Together with (66), this completes the proof. ☐

7.4 Approximate joint measurements for two components of spin

Let us apply the results above to an approximate joint measurement of two components of spin. In the classical limit, the phase space of the quantum spin system is the two-dimensional sphere $S^2 = \{q_1^2 + q_2^2 + q_3^2 = 1\} \subset \mathbb{R}^3$ equipped with the standard area form.

In what follows, we write $c_1, c_2, ...$ for positive numerical constants. The length of an interval $W \subset \mathbb{R}$ is denoted by $|W|$. Consider an open cover $W_1, ..., W_N$ of $[-1; 1]$ so that all W_i are connected intervals of the length $\leq c_1 N^{-1}$, $-1 \in W_1$, $1 \in W_N$ and $W_i \cap W_j = \emptyset$ for $|i - j| \geq 2$. Put $U_i = \{q \in S^2 \ : \ q_1 \in W_i\}$ and $V_j = \{q \in S^2 \ : \ q_2 \in W_j\}$, and consider the covers $\mathcal{U} = \{U_i\}$ and $\mathcal{V} = \{V_j\}$ of the sphere.

Theorem 7.4.

$$\mu(\mathcal{U}, \mathcal{V}) \geq c_2 N^2 \tag{67}$$

for all $N \geq N_0$, where N_0 and c_2 depend only on c_1.

Proof. Choose minimal k such that $0 \in W_k$. Consider the subset $I = \{1, ..., k\}$ of $\Omega_N = \{1, ..., N\}$. The corresponding overlap layers (see (47) above) are given by $\Lambda(\mathcal{U}, I) = \{q_1 \in W_k \cap W_{k+1}\}$ and $\Lambda(\mathcal{V}, I) = \{q_2 \in W_k \cap W_{k+1}\}$. They form a pair of spherical annuli intersecting along two quadrilaterals. Pick one of these quadrilaterals, say Π. In view of our choice of k we can assume that for sufficiently large N the quadrilateral Π lies in the domain $\{q_3 \geq 1/2\}$. In this domain, the spherical area form is given by $a(q_1, q_2) dq_1 \wedge dq_2$ with $a \leq c_3$. Therefore

$$\text{Area}(\Pi) \leq c_3 \cdot |W_k \cap W_{k+1}|^2 \leq c_4 N^{-2} \ ,$$

and thus (67) follows from (59). $\square$

This result deserves to be spelled out in more detail. Let $\{f_i\}$ and $\{g_j\}$ be any partitions of unity subordinated to the covers $\mathcal{U}$ and $\mathcal{V}$ respectively. Their quantum counterparts are given by POVMs $\{T_m(f_i)\}$ and $\{T_m(g_j)\}$. By Theorem 7.2 POVMs $\{T_m(f_i)\}$ and $\{T_m(g_j)\}$ ϵ_m-approximate von Neumann observables $T_m(q_1)$ and $T_m(q_2)$ representing the first and the second components of spin respectively with the error bar width

$$1/(4N) \leq \theta \leq 2c_1/N \; . \tag{68}$$

Here $\epsilon_m \to 0$ in the classical limit $m \to \infty$. These POVMs are jointly measurable by Proposition 3.4. Let $C^{(m)} = \{C_{ij}^{(m)}\}$, $i, j = 1, ..., N$ be such a joint observable. If the system is prepared in a pure state $[\xi] \in \mathbb{P}(H_m)$, the probability of the simultaneous registration of q_1 in the interval W_i and of q_2 in the interval W_j equals $\langle C_{ij}^{(m)}\xi, \xi\rangle$. Recall that the Planck constant $\hbar = 1/m$. As an immediate consequence of Theorem 7.4 and (68), we obtain that

$$\mathcal{N}_{in}(C^{(m)}) \cdot \theta^2 \geq c_5 \cdot \hbar \tag{69}$$

for sufficiently large quantum numbers $m = 1/\hbar$.

It is instructive to compare inequality (69) with the universal uncertainty relation for the error bar widths of approximate joint measurements. This relation has been established first for joint measurements of position and momentum observables in [12] and later on extended to general pairs of observables in [26]. For two components of spin the uncertainty relation should read

$$\theta^2 \geq c_6 \hbar \tag{70}$$

for sufficiently large m. This inequality could be extracted from Theorem 2(ii) of [26] combined with a calculation from [33] and the fact that the precision of the approximation ϵ_m goes to zero (see Theorem 7.2 above). In our context, since $\mathcal{N}_{in} \leq 1$, inequality (69) refines the uncertainty principle for error bar widths (70) for sufficiently large quantum numbers m.

8 Further directions

8.1 Does regularity of covers matter?

Let (M,ω) be a closed symplectic manifold, and let $\mathcal{U} = \{U_j\}$ be a finite open cover of M by displaceable subsets with the displacement energy $E(U_j) \le \mathcal{A}$.

Question 8.1. *Is it true that* $pb(\mathcal{U}) \ge C \cdot \mathcal{A}^{-1}$*, where the constant* C *depends only on the symplectic manifold* (M,ω)*?*

The positive answer would enable us to get lower bounds on the inherent noise of a quantum registration procedure without assuming (d,p)-regularity of the corresponding cover. A naive intuition suggests that the Poisson bracket invariant *pb* should be bigger for "irregular" covers, however, at the moment, we have neither a proof nor a counterexample.

8.2 Noise-localization uncertainty on wave-length scale

Let (M,ω) be the classical phase space (a closed symplectic manifold). Consider a (d,p)-regular cover of M of magnitude of localization $\mathcal{A}$. In what follows, d and p are fixed, while $\mathcal{A} \searrow 0$ will play the role of the small parameter. Fix a scheme of the Berezin-Toeplitz quantization $T_m : C^\infty(M) \to \mathcal{L}(H_m)$. For any partition of unity $\vec{f} = \{f_i\}$ of M subordinated to $\mathcal{U}$ consider the POVM $A^{(m)} = \{T_m(f_j)\}$ corresponding to the quantum registration problem associated to $\mathcal{U}$. The noise-localization uncertainty relation (57) reads

$$\mathcal{N}_{in}(A^{(m)}) \cdot \mathcal{A} \ge C(d,p)\hbar \quad \forall m \ge m_0 \;, \tag{71}$$

for all $m \ge m_0$. Let us emphasize that the limits $\mathcal{A} \to 0$ and $m \to \infty$ do not commute: we first fix $\mathcal{A}$, and then choose a sufficiently large m_0 which depends on various data including $\mathcal{A}$.

Assume for a moment that inequality (71) remains valid when $\mathcal{A}$ is allowed to depend on m. Since $\mathcal{N}_{in} \le 1$, this yields $\mathcal{A} \ge C\hbar$.

Question 8.2. *Does the noise-localization uncertainty relation* (71) *remain valid in the asymptotic regime when* $\mathcal{A}$ *is as small as possible, that is* $\mathcal{A} \sim \hbar$*?*

In such a regime, the dimensionless inherent noise $\mathcal{N}_{in}(A^{(m)})$ would be bounded away from zero by a positive numerical constant. Observe that if $\mathcal{A} \sim \hbar = 1/m$, the functions f_i entering the partition of unity become dependent on m as well. Therefore a rigorous justification of the above consideration would inevitably require a version of the correspondence principle for the Toeplitz operators of the form $T_m(f^{(m)})$, where the functions $f^{(m)}$ depend on the quantum number m, perhaps in a controlled way (say, they obey certain m-dependent derivative bounds.)[b] Such a version of the correspondence principle for the Berezin-Toeplitz quantization seems to be unavailable at the moment. It would be interesting to develop it by methods of pseudo-differential calculus of Toeplitz operators [14].

8.3 Approximate joint measurements in higher dimensions

In Section 7.4 we have studied approximate joint measurements of two components of spin. We started with a pair of open covers $\mathcal{U}$ and $\mathcal{V}$ associated to a discretization of these components with mesh $\sim 1/N$ and showed the the noise indicator $\mu(\mathcal{U}, \mathcal{V})$ satisfies

$$\mu(\mathcal{U}, \mathcal{V}) \geq \text{const} \cdot N^2. \tag{72}$$

The main tool used in the proof was an elementary lower bound for the pb_4-invariant on surfaces (see Section 6.1 above) established in [5]. The technique developed in [5], which involves modern symplectic methods, enables one to extend these results to higher-dimensional phase spaces.

A meaningful non-trivial example is given by a system of two spins whose phase space is the product $M = S^2 \times S^2$. A point of M is a pair (q, r) where q, r are unit vectors in $\mathbb{R}^3$. The total spin of the composed system equals $q + r$. It follows from [5] that inequality (72) holds for approximate joint measurements of two components q_1 and q_2 of the spin of the first system. It would be interesting to extend it to approximate joint measurements of two components $q_1 + q_2$ and $r_1 + r_2$ of the total spin. Even though the geometry of this problem is more involved, it sounds likely that such an extension can be obtained by methods of symplectic field theory following the lines of Section 6 of [5].

---

[b] I thank Victor Guillemin and Iosif Polterovich for useful discussions on this issue.

8.4 Localization vs. overlaps?

In the present paper we discussed two methods of detecting inherent noise, phase space localization and geometry of overlaps. The former looks as a more universal one, while the latter seems to be more efficient in situations where it is applicable at all. For instance, existence of overlap induced noise is unclear for greedy coverings of higher-dimensional manifolds. At the same time, both methods yield certain lower bounds for the noise indicator in the case of approximate joint measurements of two components of spin, and in this situation geometry of overlaps yields better results.

Is there a general recipe enabling one to choose between these two methods in specific examples? The answer to this question is unclear to us, both from the symplectic and the physical viewpoints. In fact, it would be interesting to understand a physical meaning of the overlap induced noise. For instance, does it admit an interpretation in terms of some uncertainty relation?

Acknowledgement: I am indebted to Paul Busch for pointing out [13] that the results of my recent paper [32] should extend to the case of joint measurements and for supplying me with a number of helpful bibliographical references. The present paper is a (somewhat over-sized) reply to Busch's comment. I thank Strom Borman, Victor Guillemin, Iosif Polterovich and Sobhan Seyfaddini for useful discussions and comments on the first draft of the paper.
